

# Package ‘EvidenceSynthesis’

September 9, 2022

**Type** Package

**Title** Synthesizing Causal Evidence in a Distributed Research Network

**Version** 0.3.0

**Date** 2022-09-02

**Maintainer** Martijn Schuemie <[schuemie@ohdsi.org](mailto:schuemie@ohdsi.org)>

**Description** Routines for combining causal effect estimates and study diagnostics across multiple data sites in a distributed study, without sharing patient-level data.

Allows for normal and non-normal approximations of the data-site likelihood of the effect parameter.

**SystemRequirements** Java version 8 or higher (<https://www.java.com/>)

**Depends** survival, R (>= 3.5.0)

**Imports** ggplot2, gridExtra, meta, EmpiricalCalibration, rJava, BeastJar, Cyclops (>= 3.1.0), HDInterval, coda, rlang, methods

**Suggests** knitr, rmarkdown, testthat, sn

**License** Apache License 2.0

**URL** <https://ohdsi.github.io/EvidenceSynthesis/>,  
<https://github.com/OHDSI/EvidenceSynthesis>

**BugReports** <https://github.com/OHDSI/EvidenceSynthesis/issues>

**VignetteBuilder** knitr

**RoxygenNote** 7.2.1

**Encoding** UTF-8

**NeedsCompilation** no

**Author** Martijn Schuemie [aut, cre],  
Marc A. Suchard [aut],  
Observational Health Data Science and Informatics [cph]

**Repository** CRAN

**Date/Publication** 2022-09-09 08:22:58 UTC

### approximateHierarchicalNormalPosterior

*Approximate Bayesian posterior for hierarchical Normal model*

---

#### Description

Approximate a Bayesian posterior from a set of Cyclops likelihood profiles under a hierarchical normal model using the Markov chain Monte Carlo engine BEAST.

#### Usage

```
approximateHierarchicalNormalPosterior(
  likelihoodProfiles,
  chainLength = 1100000,
  burnIn = 1e+05,
  subSampleFrequency = 100,
  effectPriorMean = 0,
  effectPriorSd = 0.5,
  nu0 = 1,
  sigma0 = 1,
  effectStartingValue = 0,
  precisionStartingValue = 1,
```

```
    seed = 1
)
```

### Arguments

<code>likelihoodProfiles</code>	List of grid likelihoods profiled with Cyclops.
<code>chainLength</code>	Number of MCMC iterations.
<code>burnIn</code>	Number of MCMC iterations to consider as burn in.
<code>subSampleFrequency</code>	Subsample frequency for the MCMC.
<code>effectPriorMean</code>	Prior mean for global parameter
<code>effectPriorSd</code>	Prior standard deviation for the global parameter
<code>nu0</code>	Prior "sample size" for precision (with precision ~ gamma( $\text{nu0}/2$ , $\text{nu0}*\sigma_0^2/2$ ))
<code>sigma0</code>	Prior "variance" for precision (with precision ~ gamma( $\text{nu0}/2$ , $\text{nu0}*\sigma_0^2/2$ ))
<code>effectStartingValue</code>	Initial value for global & local parameter
<code>precisionStartingValue</code>	Initial value for the precision
<code>seed</code>	Seed for the random number generator.

### Value

A data frame with the point estimates and 95% credible intervals for the the global and local parameter, as well as the global precision. Attributes of the data frame contain the MCMC trace for diagnostics.

### Examples

```
#TBD
```

---

`approximateLikelihood` *Approximate a likelihood function*

---

### Description

Approximate the likelihood function using a parametric (normal, skew-normal, or custom parametric), or grid approximation. The approximation does not reveal person-level information, and can therefore be shared among data sites. When counts are low, a normal approximation might not be appropriate.

**Usage**

```
approximateLikelihood(
  cyclopsFit,
  parameter = 1,
  approximation = "custom",
  bounds = c(log(0.1), log(10))
)
```

**Arguments**

<code>cyclopsFit</code>	A model fitted using the <a href="#">Cyclops::fitCyclopsModel()</a> function.
<code>parameter</code>	The parameter in the <code>cyclopsFit</code> object to profile.
<code>approximation</code>	The type of approximation. Valid options are 'normal', 'skew normal', 'custom', 'grid', or 'adaptive grid'.
<code>bounds</code>	The bounds on the effect size used to fit the approximation.

**Value**

A vector of parameters of the likelihood approximation.

**See Also**

[computeConfidenceInterval](#), [computeFixedEffectMetaAnalysis](#), [computeBayesianMetaAnalysis](#)

**Examples**

```
# Simulate some data for this example:
populations <- simulatePopulations()

cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                             data = populations[[1]],
                                             modelType = "cox")
cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
approximation <- approximateLikelihood(cyclopsFit, "x")
approximation

# (Estimates in this example will vary due to the random simulation)
```

**approximateSimplePosterior**

*Approximate simple Bayesian posterior*

**Description**

Approximate a Bayesian posterior from a Cyclops likelihood profile and normal prior using the Markov chain Monte Carlo engine BEAST.

## Usage

```
approximateSimplePosterior(
  likelihoodProfile,
  chainLength = 1100000,
  burnIn = 1e+05,
  subSampleFrequency = 100,
  priorMean = 0,
  priorSd = 0.5,
  startingValue = 0,
  seed = 1
)
```

## Arguments

<code>likelihoodProfile</code>	Named vector containing grid likelihood data from Cyclops.
<code>chainLength</code>	Number of MCMC iterations.
<code>burnIn</code>	Number of MCMC iterations to consider as burn in.
<code>subSampleFrequency</code>	Subsample frequency for the MCMC.
<code>priorMean</code>	Prior mean for the regression parameter
<code>priorSd</code>	Prior standard deviation for the regression parameter
<code>startingValue</code>	Initial state for regression parameter
<code>seed</code>	Seed for the random number generator.

## Value

A data frame with the point estimates and 95% credible intervals for the regression parameter. Attributes of the data frame contain the MCMC trace for diagnostics.

## Examples

```
# Simulate some data for this example:
population <- simulatePopulations(createSimulationSettings(nSites = 1))[[1]]

# Fit a Cox regression at each data site, and approximate likelihood function:
cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                             data = population,
                                             modelType = "cox")
cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
likelihoodProfile <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "grid")

# Run MCMC
mcmcTraces <- approximateSimplePosterior(likelihoodProfile = likelihoodProfile,
                                            priorMean = 0, priorSd = 100)

# Report posterior expectation
mean(mcmcTraces$theta)
```

---

```
# (Estimates in this example will vary due to the random simulation)
```

---

---

### computeBayesianMetaAnalysis

*Compute a Bayesian random-effects meta-analysis*

---

## Description

Compute a Bayesian meta-analysis using the Markov chain Monte Carlo (MCMC) engine BEAST. A normal and half-normal prior are used for the mu and tau parameters, respectively, with standard deviations as defined by the priorSd argument.

## Usage

```
computeBayesianMetaAnalysis(
  data,
  chainLength = 1100000,
  burnIn = 1e+05,
  subSampleFrequency = 100,
  priorSd = c(2, 0.5),
  alpha = 0.05,
  seed = 1,
  robust = FALSE
)
```

## Arguments

data	A data frame containing either normal, skew-normal, custom parametric, or grid likelihood data, with one row per database.
chainLength	Number of MCMC iterations.
burnIn	Number of MCMC iterations to consider as burn in.
subSampleFrequency	Subsample frequency for the MCMC.
priorSd	A two-dimensional vector with the standard deviation of the prior for mu and tau, respectively.
alpha	The alpha (expected type I error) used for the credible intervals.
seed	The seed for the random number generator.
robust	Whether or not to use a t-distribution model (default: FALSE)

## Value

A data frame with the point estimates and 95% credible intervals for the mu and tau parameters (the mean and standard deviation of the distribution from which the per-site effect sizes are drawn). Attributes of the data frame contain the MCMC trace and the detected approximation type.

**See Also**

[approximateLikelihood](#), [computeFixedEffectMetaAnalysis](#)

**Examples**

```
# Simulate some data for this example:
populations <- simulatePopulations()

# Fit a Cox regression at each data site, and approximate likelihood function:
fitModelInDatabase <- function(population) {
  cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                              data = population,
                                              modelType = "cox")
  cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
  approximation <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "custom")
  return(approximation)
}
approximations <- lapply(populations, fitModelInDatabase)
approximations <- do.call("rbind", approximations)

# At study coordinating center, perform meta-analysis using per-site approximations:
estimate <- computeBayesianMetaAnalysis(approximations)
estimate

# (Estimates in this example will vary due to the random simulation)
```

**computeConfidenceInterval**

*Compute the point estimate and confidence interval given a likelihood function approximation*

**Description**

Compute the point estimate and confidence interval given a likelihood function approximation

**Usage**

```
computeConfidenceInterval(approximation, alpha = 0.05)
```

**Arguments**

- approximation An approximation of the likelihood function as fitted using the [approximateLikelihood\(\)](#) function.
- alpha The alpha (expected type I error).

**Details**

Compute the point estimate and confidence interval given a likelihood function approximation.

**Value**

A data frame containing the point estimate, and upper and lower bound of the confidence interval.

**Examples**

```
# Simulate some data for this example:  
populations <- simulatePopulations()  
  
cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),  
                                         data = populations[[1]],  
                                         modelType = "cox")  
cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)  
approximation <- approximateLikelihood(cyclopsFit, "x")  
computeConfidenceInterval(approximation)
```

**computeFixedEffectMetaAnalysis**  
*Compute a fixed-effect meta-analysis*

**Description**

Compute a fixed-effect meta-analysis using a choice of various likelihood approximations.

**Usage**

```
computeFixedEffectMetaAnalysis(data, alpha = 0.05)
```

**Arguments**

<b>data</b>	A data frame containing either normal, skew-normal, custom parametric, or grid likelihood data. One row per database.
<b>alpha</b>	The alpha (expected type I error) used for the confidence intervals.

**Value**

The meta-analytic estimate, expressed as the point estimate hazard ratio (rr), its 95 percent confidence interval (lb, ub), as well as the log of the point estimate (logRr), and the standard error (seLogRr).

**See Also**

[approximateLikelihood](#), [computeBayesianMetaAnalysis](#)

## Examples

```
# Simulate some data for this example:
populations <- simulatePopulations()

# Fit a Cox regression at each data site, and approximate likelihood function:
fitModelInDatabase <- function(population) {
  cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                              data = population,
                                              modelType = "cox")
  cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
  approximation <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "custom")
  return(approximation)
}
approximations <- lapply(populations, fitModelInDatabase)
approximations <- do.call("rbind", approximations)

# At study coordinating center, perform meta-analysis using per-site approximations:
computeFixedEffectMetaAnalysis(approximations)

# (Estimates in this example will vary due to the random simulation)
```

## createSimulationSettings

*Create simulation settings*

## Description

Create an object specifying a simulation. Currently only Cox proportional hazard models are supported.

## Usage

```
createSimulationSettings(
  nSites = 5,
  n = 10000,
  treatedFraction = 0.2,
  nStrata = 10,
  minBackgroundHazard = 2e-07,
  maxBackgroundHazard = 2e-05,
  hazardRatio = 2,
  randomEffectSd = 0
)
```

## Arguments

nSites	Number of database sites to simulate.
n	Number of subjects per site. Either a single number, or a vector of length nSites.

**treatedFraction**  
 Fraction of subjects that is treated. Either a single number, or a vector of length nSites.

**nStrata** Number of strata per site. Either a single number, or a vector of length nSites.

**minBackgroundHazard** Minimum background hazard. Either a single number, or a vector of length nSites.

**maxBackgroundHazard** Maximum background hazard. Either a single number, or a vector of length nSites.

**hazardRatio** Hazard ratio.

**randomEffectSd** Standard deviation of the log(hazardRatio). Fixed effect if equal to 0.

## Value

An object of type `simulationSettings`, to be used in the [simulatePopulations\(\)](#) function.

## See Also

[simulatePopulations](#)

## Examples

```
settings <- createSimulationSettings(nSites = 1, hazardRatio = 2)
populations <- simulatePopulations(settings)

# Fit a Cox regression for the simulated data site:
cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                             data = populations[[1]],
                                             modelType = "cox")
cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
coef(cyclopsFit)

# (Estimates in this example will vary due to the random simulation)
```

## Description

A custom function to approximate a log likelihood function

## Usage

```
customFunction(x, mu, sigma, gamma)
```

**Arguments**

<code>x</code>	The log(hazard ratio) for which to approximate the log likelihood.
<code>mu</code>	The position parameter.
<code>sigma</code>	The scale parameter.
<code>gamma</code>	The skew parameter.

**Details**

A custom parametric function designed to approximate the shape of the Cox log likelihood function.  
When `gamma = 0` this function is the normal distribution.

**Value**

The approximate log likelihood for the given `x`.

**Examples**

```
customFunction(x = 0:3, mu = 0, sigma = 1, gamma = 0)
```

`plotCovariateBalances` *Plot covariate balances*

**Description**

Plots the covariate balance before and after matching for multiple data sources.

**Usage**

```
plotCovariateBalances(
  balances,
  labels,
  threshold = 0,
  beforeLabel = "Before matching",
  afterLabel = "After matching",
  fileName = NULL
)
```

**Arguments**

<code>balances</code>	A list of covariate balance objects as created using the <code>computeCovariateBalance()</code> function in the <code>CohortMethod</code> package. Each balance object is expected to be a data frame with at least these two columns: <code>beforeMatchingStdDiff</code> and <code>afterMatchingStdDiff</code> .
<code>labels</code>	A vector containing the labels for the various sources.
<code>threshold</code>	Show a threshold value for the standardized difference.

**beforeLabel** Label for before matching / stratification / trimming.  
**afterLabel** Label for after matching / stratification / trimming.  
**fileName** Name of the file where the plot should be saved, for example 'plot.png'. See the function [ggplot2::ggsave](#) for supported file formats.

## Details

Creates a plot showing the covariate balance before and after matching. Balance distributions are displayed as box plots combined with scatterplots.

## Value

A Ggplot object. Use the [ggplot2::ggsave](#).

## Examples

```
# Some example data:
balance1 <- data.frame(beforeMatchingStdDiff = rnorm(1000, 0.1, 0.1),
                        afterMatchingStdDiff = rnorm(1000, 0, 0.01))
balance2 <- data.frame(beforeMatchingStdDiff = rnorm(1000, 0.2, 0.1),
                        afterMatchingStdDiff = rnorm(1000, 0, 0.05))
balance3 <- data.frame(beforeMatchingStdDiff = rnorm(1000, 0, 0.1),
                        afterMatchingStdDiff = rnorm(1000, 0, 0.03))
plotCovariateBalances(balances = list(balance1, balance2, balance3),
                      labels = c("Site A", "Site B", "Site C"))
```

**plotEmpiricalNulls** *Plot empirical null distributions*

## Description

Plot the empirical null distribution for multiple data sources.

## Usage

```
plotEmpiricalNulls(
  logRr,
  seLogRr,
  labels,
  xLabel = "Relative risk",
  limits = c(0.1, 10),
  showCis = TRUE,
  fileName = NULL
)
```

## Arguments

<code>logRr</code>	A numeric vector of effect estimates for the negative controls on the log scale.
<code>seLogRr</code>	The standard error of the log of the effect estimates. Hint: often the standard error = $(\log(\text{lower bound 95 percent confidence interval}) - \log(\text{effect estimate})) / \text{qnorm}(0.025)$ .
<code>labels</code>	A vector containing the labels for the various sources. Should be of equal length as <code>logRr</code> and <code>seLogRr</code> .
<code>xLabel</code>	The label on the x-axis: the name of the effect estimate.
<code>limits</code>	The limits of the effect size axis.
<code>showCis</code>	Show the 95 percent confidence intervals on the null distribution and distribution parameter estimates?
<code>fileName</code>	Name of the file where the plot should be saved, for example ' <code>plot.png</code> '. See the function <a href="#">ggplot2::ggsave()</a> for supported file formats.

## Details

Creates a plot showing the empirical null distributions. Distributions are shown as mean plus minus one standard deviation, as well as a distribution plot.

## Value

A Ggplot object. Use the [ggplot2::ggsave\(\)](#) function to save to file.

## See Also

[EmpiricalCalibration::fitNull](#), [EmpiricalCalibration::fitMcmcNull](#)

## Examples

```
# Some example data:
site1 <- EmpiricalCalibration::simulateControls(n = 50, mean = 0, sd = 0.1, trueLogRr = 0)
site1$label <- "Site 1"
site2 <- EmpiricalCalibration::simulateControls(n = 50, mean = 0.1, sd = 0.2, trueLogRr = 0)
site2$label <- "Site 2"
site3 <- EmpiricalCalibration::simulateControls(n = 50, mean = 0.15, sd = 0.25, trueLogRr = 0)
site3$label <- "Site 3"
sites <- rbind(site1, site2, site3)

plotEmpiricalNulls(logRr = sites$logRr, seLogRr = sites$seLogRr, labels = sites$label)
```

**plotLikelihoodFit**      *Plot the likelihood approximation*

---

## Description

Plot the likelihood approximation

## Usage

```
plotLikelihoodFit(
  approximation,
  cyclopsFit,
  parameter = "x",
  logScale = TRUE,
  xLabel = "Hazard Ratio",
  limits = c(0.1, 10),
  fileName = NULL
)
```

## Arguments

<code>approximation</code>	An approximation of the likelihood function as fitted using the <a href="#">approximateLikelihood()</a> function.
<code>cyclopsFit</code>	A model fitted using the <a href="#">Cyclops::fitCyclopsModel()</a> function.
<code>parameter</code>	The parameter in the cyclopsFit object to profile.
<code>logScale</code>	Show the y-axis on the log scale?
<code>xLabel</code>	The title of the x-axis.
<code>limits</code>	The limits on the x-axis.
<code>fileName</code>	Name of the file where the plot should be saved, for example 'plot.png'. See the function <a href="#">ggplot2::ggsave</a> in the ggplot2 package for supported file formats.

## Details

Plots the (log) likelihood and the approximation of the likelihood. Allows for reviewing the approximation.

## Value

A Ggplot object. Use the [ggplot2::ggsave](#) function to save to file.

## Examples

```
# Simulate a single database population:
population <- simulatePopulations(createSimulationSettings(nSites = 1))[[1]]

# Approximate the likelihood:
cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                             data = population,
                                             modelType = "cox")
cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
approximation <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "custom")

plotLikelihoodFit(approximation, cyclopsFit, parameter = "x")
```

**plotMcmcTrace**

*Plot MCMC trace*

## Description

Plot MCMC trace

## Usage

```
plotMcmcTrace(
  estimate,
  showEstimate = TRUE,
  dataCutoff = 0.01,
  fileName = NULL
)
```

## Arguments

<code>estimate</code>	An object as generated using the <a href="#">computeBayesianMetaAnalysis()</a> function.
<code>showEstimate</code>	Show the parameter estimates (mode) and 95 percent confidence intervals?
<code>dataCutoff</code>	This fraction of the data at both tails will be removed.
<code>fileName</code>	Name of the file where the plot should be saved, for example 'plot.png'. See the function <a href="#">ggplot2::ggsave</a> in the ggplot2 package for supported file formats.

## Details

Plot the samples of the posterior distribution of the mu and tau parameters. Samples are taken using Markov-chain Monte Carlo (MCMC).

## Value

A Ggplot object. Use the [ggplot2::ggsave](#) function to save to file.

**See Also**

[computeBayesianMetaAnalysis](#)

**Examples**

```
# Simulate some data for this example:
populations <- simulatePopulations()

# Fit a Cox regression at each data site, and approximate likelihood function:
fitModelInDatabase <- function(population) {
  cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                             data = population,
                                             modelType = "cox")
  cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
  approximation <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "custom")
  return(approximation)
}
approximations <- lapply(populations, fitModelInDatabase)
approximations <- do.call("rbind", approximations)

# At study coordinating center, perform meta-analysis using per-site approximations:
estimate <- computeBayesianMetaAnalysis(approximations)
plotMcmcTrace(estimate)
```

**plotMetaAnalysisForest**

*Create a forest plot*

**Description**

Creates a forest plot of effect size estimates, including the summary estimate.

**Usage**

```
plotMetaAnalysisForest(
  data,
  labels,
  estimate,
  xLabel = "Relative risk",
  summaryLabel = "Summary",
  limits = c(0.1, 10),
  alpha = 0.05,
  fileName = NULL
)
```

## Arguments

<code>data</code>	A data frame containing either normal, skew-normal, custom parametric, or grid likelihood data. One row per database.
<code>labels</code>	A vector of labels for the data sources.
<code>estimate</code>	The meta-analytic estimate as created using either <code>[computeFixedEffectMetaAnalysis()]</code> or <code>[computeBayesianMetaAnalysis()]</code> function.
<code>xLabel</code>	The label on the x-axis: the name of the effect estimate.
<code>summaryLabel</code>	The label for the meta-analytic estimate.
<code>limits</code>	The limits of the effect size axis.
<code>alpha</code>	The alpha (expected type I error).
<code>fileName</code>	Name of the file where the plot should be saved, for example <code>'plot.png'</code> . See the function <a href="#">ggplot2::ggsave</a> if for supported file formats.

## Details

Creates a forest plot of effect size estimates, including a meta-analysis estimate.

## Value

A Ggplot object. Use the [ggplot2::ggsave](#) function to save to file.

## Examples

```
# Simulate some data for this example:
populations <- simulatePopulations()
labels <- paste("Data site", LETTERS[1:length(populations)])

# Fit a Cox regression at each data site, and approximate likelihood function:
fitModelInDatabase <- function(population) {
  cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                              data = population,
                                              modelType = "cox")
  cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
  approximation <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "custom")
  return(approximation)
}
approximations <- lapply(populations, fitModelInDatabase)
approximations <- do.call("rbind", approximations)

# At study coordinating center, perform meta-analysis using per-site approximations:
estimate <- computeBayesianMetaAnalysis(approximations)
plotMetaAnalysisForest(approximations, labels, estimate)

# (Estimates in this example will vary due to the random simulation)
```

**plotPerDbMcmcTrace**      *Plot MCMC trace for individual databases*

## Description

Plot MCMC trace for individual databases

## Usage

```
plotPerDbMcmcTrace(
  estimate,
  showEstimate = TRUE,
  dataCutoff = 0.01,
  fileName = NULL
)
```

## Arguments

<code>estimate</code>	An object as generated using the <a href="#">computeBayesianMetaAnalysis()</a> function.
<code>showEstimate</code>	Show the parameter estimates (mode) and 95 percent confidence intervals?
<code>dataCutoff</code>	This fraction of the data at both tails will be removed.
<code>fileName</code>	Name of the file where the plot should be saved, for example 'plot.png'. See the function <a href="#">ggplot2::ggsave</a> in the ggplot2 package for supported file formats.

## Details

Plot the samples of the posterior distribution of the theta parameter (the estimated log hazard ratio) at each site. Samples are taken using Markov-chain Monte Carlo (MCMC).

## Value

A Ggplot object. Use the [ggplot2::ggsave](#) function to save to file.

## See Also

[computeBayesianMetaAnalysis](#)

## Examples

```
# Simulate some data for this example:
populations <- simulatePopulations()

# Fit a Cox regression at each data site, and approximate likelihood function:
fitModelInDatabase <- function(population) {
  cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                              data = population,
                                              modelType = "cox")
  cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
```

```

approximation <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "custom")
return(approximation)
}
approximations <- lapply(populations, fitModelInDatabase)
approximations <- do.call("rbind", approximations)

# At study coordinating center, perform meta-analysis using per-site approximations:
estimate <- computeBayesianMetaAnalysis(approximations)
plotPerDbMcmcTrace(estimate)

```

`plotPerDbPosterior`     *Plot posterior density per database*

## Description

Plot posterior density per database

## Usage

```

plotPerDbPosterior(
  estimate,
  showEstimate = TRUE,
  dataCutoff = 0.01,
  fileName = NULL
)

```

## Arguments

<code>estimate</code>	An object as generated using the <a href="#">computeBayesianMetaAnalysis()</a> function.
<code>showEstimate</code>	Show the parameter estimates (mode) and 95 percent confidence intervals?
<code>dataCutoff</code>	This fraction of the data at both tails will be removed.
<code>fileName</code>	Name of the file where the plot should be saved, for example 'plot.png'. See the function <a href="#">ggplot2::ggsave</a> in the ggplot2 package for supported file formats.

## Details

Plot the density of the posterior distribution of the theta parameter (the estimated log hazard ratio) at each site.

## Value

A Ggplot object. Use the [ggplot2::ggsave](#) function to save to file.

## Examples

```
# Simulate some data for this example:
populations <- simulatePopulations()

# Fit a Cox regression at each data site, and approximate likelihood function:
fitModelInDatabase <- function(population) {
  cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                              data = population,
                                              modelType = "cox")
  cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
  approximation <- approximateLikelihood(cyclopsFit, parameter = "x", approximation = "custom")
  return(approximation)
}
approximations <- lapply(populations, fitModelInDatabase)
approximations <- do.call("rbind", approximations)

# At study coordinating center, perform meta-analysis using per-site approximations:
estimate <- computeBayesianMetaAnalysis(approximations)
plotPerDbPosterior(estimate)
```

**plotPosterior**      *Plot posterior density*

## Description

Plot posterior density

## Usage

```
plotPosterior(
  estimate,
  showEstimate = TRUE,
  dataCutoff = 0.01,
  fileName = NULL
)
```

## Arguments

<code>estimate</code>	An object as generated using the <a href="#">computeBayesianMetaAnalysis()</a> function.
<code>showEstimate</code>	Show the parameter estimates (mode) and 95 percent confidence intervals?
<code>dataCutoff</code>	This fraction of the data at both tails will be removed.
<code>fileName</code>	Name of the file where the plot should be saved, for example 'plot.png'. See the function <a href="#">ggplot2:ggsave</a> in the ggplot2 package for supported file formats.

## Details

Plot the density of the posterior distribution of the mu and tau parameters.

**Value**

A Ggplot object. Use the [ggplot2::ggsave](#) function to save to file.

**See Also**

[computeBayesianMetaAnalysis](#)

**Examples**

```
# Simulate some data for this example:  
populations <- simulatePopulations()  
  
# Fit a Cox regression at each data site, and approximate likelihood function:  
fitModelInDatabase <- function(population) {  
  cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),  
                                             data = population,  
                                             modelType = "cox")

  return(approximation)  
}  
approximations <- lapply(populations, fitModelInDatabase)  
approximations <- do.call("rbind", approximations)  
  
# At study coordinating center, perform meta-analysis using per-site approximations:  
estimate <- computeBayesianMetaAnalysis(approximations)  
plotPosterior(estimate)
```

---

plotPreparedPs

*Plot the propensity score distribution*

---

**Description**

Plot the propensity score distribution

**Usage**

```
plotPreparedPs(  
  preparedPsPlots,  
  labels,  
  treatmentLabel = "Target",  
  comparatorLabel = "Comparator",  
  fileName = NULL  
)
```

## Arguments

<code>preparedPsPlots</code>	list of prepared propensity score data as created by the <a href="#">preparePsPlot()</a> function.
<code>labels</code>	A vector containing the labels for the various sources.
<code>treatmentLabel</code>	A label to us for the treated cohort.
<code>comparatorLabel</code>	A label to us for the comparator cohort.
<code>fileName</code>	Name of the file where the plot should be saved, for example 'plot.png'. See the function <a href="#">ggplot2::ggsave</a> for supported file formats.

## Value

A ggplot object. Use the [ggplot2::ggsave](#) function to save to file in a different format.

## See Also

[preparePsPlot](#)

## Examples

```
# Simulate some data for this example:
treatment <- rep(0:1, each = 100)
propensityScore <- c(rnorm(100, mean = 0.4, sd = 0.25), rnorm(100, mean = 0.6, sd = 0.25))
data <- data.frame(treatment = treatment, propensityScore = propensityScore)
data <- data[data$propensityScore > 0 & data$propensityScore < 1, ]
preparedPlot <- preparePsPlot(data)

# Just reusing the same data three times for demonstration purposes:
preparedPsPlots <- list(preparedPlot, preparedPlot, preparedPlot)
labels <- c("Data site A", "Data site B", "Data site C")

plotPreparedPs(preparedPsPlots, labels)
```

`preparePsPlot`

*Prepare to plot the propensity score distribution*

## Description

Prepare to plot the propensity (or preference) score distribution. It computes the distribution, so the output does not contain person-level data.

## Usage

```
preparePsPlot(data, unfilteredData = NULL, scale = "preference")
```

## Arguments

data	A data frame with at least the two columns described below
unfilteredData	To be used when computing preference scores on data from which subjects have already been removed, e.g. through trimming and/or matching. This data frame should have the same structure as data.
scale	The scale of the graph. Two scales are supported: <code>scale = 'propensity'</code> or <code>scale = 'preference'</code> . The preference score scale is defined by Walker et al. (2013).

## Details

The data frame should have a least the following two columns:

- **treatment** (integer): Column indicating whether the person is in the treated (1) or comparator (0) group. - **propensityScore** (numeric): Propensity score.

## Value

A data frame describing the propensity score (or preference score) distribution at 100 equally-spaced points.

## References

## Examples

```
# Simulate some data for this example:  
treatment <- rep(0:1, each = 100)  
propensityScore <- c(rnorm(100, mean = 0.4, sd = 0.25), rnorm(100, mean = 0.6, sd = 0.25))  
data <- data.frame(treatment = treatment, propensityScore = propensityScore)  
data <- data[data$propensityScore > 0 & data$propensityScore < 1, ]  
  
preparedPlot <- preparePsPlot(data)
```

`simulatePopulations`    *Simulate survival data for multiple databases*

## Description

Simulate survival data for multiple databases

## Usage

```
simulatePopulations(settings = createSimulationSettings())
```

## Arguments

<code>settings</code>	An object of type <code>simulationSettings</code> , created by the <a href="#">createSimulationSettings()</a> function.
-----------------------	---

## Value

A object of class `simulation`, which is a list of populations, each a data frame with columns `rowId`, `stratumId`, `x`, `time`, and `y`.

## Examples

```
settings <- createSimulationSettings(nSites = 1, hazardRatio = 2)
populations <- simulatePopulations(settings)

# Fit a Cox regression for the simulated data site:
cyclopsData <- Cyclops::createCyclopsData(Surv(time, y) ~ x + strata(stratumId),
                                             data = populations[[1]],
                                             modelType = "cox")
cyclopsFit <- Cyclops::fitCyclopsModel(cyclopsData)
coef(cyclopsFit)

# (Estimates in this example will vary due to the random simulation)
```

`skewNormal`

*The skew normal function to approximate a log likelihood function*

## Description

The skew normal function to approximate a log likelihood function

## Usage

```
skewNormal(x, mu, sigma, alpha)
```

**Arguments**

x	The log(hazard ratio) for which to approximate the log likelihood.
mu	The position parameter.
sigma	The scale parameter.
alpha	The skew parameter.

**Details**

The skew normal function. When alpha = 0 this function is the normal distribution.

**Value**

The approximate log likelihood for the given x.

**References**

Azzalini, A. (2013). The Skew-Normal and Related Families. Institute of Mathematical Statistics Monographs. Cambridge University Press.

**Examples**

```
skewNormal(x = 0:3, mu = 0, sigma = 1, alpha = 0)
```

---

supportsJava8

*Determine if Java virtual machine supports Java*

---

**Description**

Tests Java virtual machine (JVM) java.version system property to check if version >= 8.

**Usage**

```
supportsJava8()
```

**Value**

Returns TRUE if JVM supports Java >= 8.

**Examples**

```
supportsJava8()
```
