Package 'memoria'

May 17, 2019

Type Package

Title Quantifying Ecological Memory in Palaeoecological Datasets and Other Long Time-Series
Version 1.0.0
Author Blas M. Benito
Maintainer Blas M. Benito blasbenito@gmail.com>
Description Tools to quantify ecological memory in long time-series with Random Forest models (Breiman 2001 <doi:10.1023 a:1010933404324="">) fitted with the 'ranger' library (Wright and Ziegler 2017 <doi:10.18637 jss.v077.i01="">). Particularly oriented to palaeoeco logical datasets and simulated pollen curves produced by the 'virtualPollen' package, but also applicable to other long time-series involving a set of environmental drivers and a biotic response.</doi:10.18637></doi:10.1023>

climate

Index

Dataframe with palaeoclimatic data.

Description

A dataframe containing palaeoclimate data at 1 ky temporal resolution with the following columns:

Usage

data(climate)

Format

dataframe with 6 columns and 800 rows.

Details

- age in kiloyears before present (ky BP).
- temperatureAverage average annual temperature in Celsius degrees.
- rainfallAverage average annual precipitation in milimetres per day (mm/day).
- temperature Warmest Month average temperature of the warmest month, in Celsius degrees.
- temperatureColdestMonth average temperature of the coldest month, in Celsius degrees.
- *oxigenIsotope* delta O18, global ratio of stable isotopes in the sea floor, see http://lorraine-lisiecki.com/stack.html for further details.

computeMemory 3

computeMemory

Quantifies ecological memory with Random Forest.

Description

Takes the oputput of prepareLaggedData to fit the following model with Random Forest:

```
p_t = p_{t-1} + \dots + p_{t-n} + d_t + d_{t-1} + \dots + d_{t-n} + r where:
```

- d is a driver (several drivers can be added).
- t is the time of any given value of the response p.
- t-1 is the lag number 1 (in time units).
- $p_{t-1} + ... + p_{t-n}$ represents the endogenous component of ecological memory.
- $d_{t-1} + ... + d_{t-n}$ represents the exogenous component of ecological memory.
- d_t represents the concurrent effect of the driver over the response.
- r represents a column of random values, used to test the significance of the variable importance scores returned by Random Forest.

Usage

```
computeMemory(
  lagged.data = NULL,
  drivers = NULL,
  response = "Response",
  add.random = TRUE,
  random.mode = "autocorrelated",
  repetitions = 10,
  subset.response = "none",
  min.node.size = 5,
  num.trees = 2000,
  mtry = 2
)
```

Arguments

lagged.data	a lagged dataset resulting from ${\tt prepareLaggedData}.$ See palaeodataLagged as example.
drivers	a character string or vector of character strings with variables to be used as predictors in the model (i.e. c("Suitability", "Driver.A")). Important: drivers names must not have the character "_".
response	character string, name of the response variable (typically, "Response_0").
add.random	if TRUE, adds a random term to the model, useful to assess the significance of

the variable importance scores.

4 computeMemory

random.mode either "white.noise" or "autocorrelated". See details. repetitions integer, number of random forest models to fit.

subset.response

character string with values "up", "down" or "none", triggers the subsetting of the input dataset. "up" only models memory on cases where the response's trend is positive, "down" selectes cases with negative trends, and "none" selects

all cases.

min.node.size integer, argument of the ranger function. Minimal number of samples to be

allocated in a terminal node. Default is 5.

num. trees integer, argument of the ranger function. Number of regression trees to be fitted

(size of the forest). Default is 2000.

mtry integer, argument of the ranger function. Number of variables to possibly split

at in each node. Default is 2.

Details

This function uses the ranger package to fit Random Forest models. Please, check the help of the ranger function to better understand how Random Forest is parameterized in this library. This function fits the model explained above as many times as defined in the argument repetitions. To test the statistical significance of the variable importance scores returned by random forest, on each repetition the model is fitted with a different r (random) term. If random.mode equals "autocorrelated", the random term will have a temporal autocorrelation, and if it equals "white.noise", it will be a pseudo-random sequence of numbers generated with rnorm, with no temporal autocorrelation. The importance of the random sequence (as computed by random forest) is stored for each model run, and used as a benchmark to assess the importance of the other predictors used in the models. Importance values of other predictors that are above the median of the importance of the random term should be interpreted as non-random, and therefore, significant.

Value

A list with 4 slots:

- memory dataframe with five columns:
 - Variable character, names and lags of the different variables used to model ecological memory.
 - median numeric, median importance across repetitions of the given Variable according to Random Forest.
 - sd numeric, standard deviation of the importance values of the given Variable across repetitions.
 - min and max numeric, percentiles 0.05 and 0.95 of importance values of the given Variable across repetitions.
- R2 vector, values of pseudo R-squared value obtained for the Random Forest model fitted on each repetition. Pseudo R-squared is the Pearson correlation beteween the observed and predicted data.
- prediction dataframe, with the same columns as the dataframe in the slot memory, with the median and confidence intervals of the predictions of all random forest models fitted.
- multicollinearity multicollinearity analysis on the input data performed with vif. A vif value higher than 5 indicates that the given variable is highly correlated with other variables.

Examples

```
#loading data
data(palaeodataLagged)

memory.output <- computeMemory(
  lagged.data = palaeodataLagged,
  drivers = c("climate.temperatureAverage", "climate.rainfallAverage"),
  response = "Response",
  add.random = TRUE,
  random.mode = "autocorrelated",
  repetitions = 10,
  subset.response = "none"
)

str(memory.output)
str(memory.output)
#plotting output
plotMemory(memory.output = memory.output)</pre>
```

experimentToTable

Turns the outcome of runExperiment into a long table.

Description

Takes the output of runExperiment, extracts the dataframes containing the ecological memory patterns generated by computeMemory, and binds them together into a single dataframe ready for further analyses or plotting.

Usage

```
experimentToTable(
  experiment.output = NULL,
  parameters.file = NULL,
  sampling.names = NULL,
  R2 = TRUE
)
```

Arguments

```
experiment.output
list, output of runExperiment.

parameters.file
dataframe of simulation parameters.

sampling.names vector of character strings with the names of the columns of simulations.file.

R2 boolean. If TRUE, the average pseudo R-squared of the random forest models used to analyze the ecological memory pattern of the virtual taxa are shown with the taxon traits.
```

Details

This function is used internally by plotExperiment, but it is also available to users in case they want to do other kinds of analyses or plots with the data.

Value

A dataframe.

runExperiment, plotExperiment

 ${\it extractMemoryFeatures}$ ${\it Extracts ecological memory features on the output of compute Memory.}$

Description

It computes the following features of the ecological memory patterns returned by computeMemory:

• memory strength maximum difference in relative importance between each component (endogenous, exogenous, and concurrent) and the median of the random component. This is computed for exogenous, endogenous, and concurrent effect.

- memory length proportion of lags over which the importance of a memory component is above the median of the random component. This is only computed for endogenous and exogenous memory.
- dominance proportion of the lags above the median of the random term over which a memory component has a higher importance than the other component. This is only computed for endogenous and exogenous memory.

Usage

```
extractMemoryFeatures(
memory.pattern = NULL,
exogenous.component = NULL,
endogenous.component = NULL,
sampling.subset = NULL,
scale.strength = TRUE
)
```

Arguments

memory.pattern either a list resulting from computeMemory, or a dataframe with memory patterns of several taxa generated by experimentToTable.

exogenous.component

character string or vector of character strings, name of the variable or variables defining the exogenous component.

endogenous.component

character string, string, name of the variable defining the endogenous component. If the data was generated by prepareLaggedData, endogenous.component would usually be "Response".

sampling.subset

only relevant when analysis.output is the result of runExperiment. Character string with the name of the column of the list with the simulation outcomes.

scale.strength boolean. If TRUE, the strength of the ecological memory components, which has the same units as the importance scores yielded by Random Forest (percentage of increment in mean squared error when a variable is permuted), is scaled between 0 and 1.

Details

Warning: this function only works when only one exogenous component (driver) is used to define the model in computeMemory. If more than one driver is provided throught the argument exogenous.component, the maximum importance scores of all exogenous variables is considered. In other words, the importance of exogenous variables is not additive.

Value

A dataframe with 8 columns and 1 row if memory pattern is the output of computeMemory and 13 columns and as many rows as taxa are in the input if it is the output of experimentToTable. The columns are:

- label character string to identify the taxon. It either inherits its values from experimentToTable, or sets the default ID as "1".
- *strength.endogenous* numeric in the range [0, 100], in importance units (percentage of increment in the mean squared error of the random forest model if the variable is permuted) difference between the maximum importance of the endogenous component at any lag and the median of the random component (see details in computeMemory)
- *strength.exogenous* numeric in the range [0, 100], same as above, but for the exogenous component.
- *strenght.concurrent* numeric in the range [0, 100], same as above, but for the concurrent component (driver at lag 0).
- *length.endogenous* numeric in the range [0, 100], proportion of lags over which the importance of the endogenous memory component is above the median of the random component.
- *length.exogenous* numeric in the range [0, 1], same as above but for the exogenous memory component.
- *dominance.endogenous* numeric in the range [0, 1], proportion of the lags above the median of the random term over which a the endogenous memory component has a higher importance than the exogenous component.
- dominance.exogenous, opposite as above.
- *maximum.age*, numeric. As every column after this one, only provided if memory.pattern is the output of experimentToTable. Trait of the given taxon.
- fecundity numeric, trait of the given taxon.
- niche.A.mean numeric, trait of the given taxon.
- *niche.A.sd* numeric, trait of the given taxon.
- sampling numeric, trait of the given taxon.

computeMemory

Examples

```
#loading example data
data(palaeodataMemory)

#computing ecological memory features
memory.features <- extractMemoryFeatures(
   memory.pattern = palaeodataMemory,
   exogenous.component = c(
   "climate.temperatureAverage",
   "climate.rainfallAverage"
   ),</pre>
```

mergePalaeoData 9

```
endogenous.component = "Response",
sampling.subset = NULL,
scale.strength = TRUE
)
```

mergePalaeoData

Merges palaeoecological datasets with different time resolution.

Description

It merges palaeoecological datasets with different time intervals between consecutive samples into a single dataset with samples separated by regular time intervals defined by the user

Usage

```
mergePalaeoData(
  datasets.list = NULL,
  time.column = NULL,
  interpolation.interval = NULL
)
```

Arguments

datasets.list list of dataframes, as in datasets.list = list(climate = climate.dataframe, pollen = pollen.org)

The provided dataframes must have an age/time column with the same column name and the same units of time. Non-numeric columns in these dataframes are ignored.

time.column character string, name of the time/age column of the datasets provided in datasets.list.

interpolation.interval temporal resolution of the output data, in the same units as the age/time columns of the input data

Details

This function fits a loess model of the form $y \sim x$, where y is any column given by columns.to.interpolate and x is the column given by the time.column argument. The model is used to interpolate column y on a regular time series of intervals equal to interpolation.interval. All columns in every provided dataset go through this process to generate the final data with samples separated by regular time intervals. Non-numeric columns are ignored, and absent from the output dataframe.

Value

A dataframe with every column of the initial dataset interpolated to a regular time grid of resolution defined by interpolation.interval. Column names follow the form datasetName.columnName, so the origin of columns can be tracked.

10 palaeodata

Author(s)

Blas M. Benito

blasbenito@gmail.com>

Examples

```
#loading data
data(pollen)
data(climate)

x <- mergePalaeoData(
    datasets.list = list(
        pollen=pollen,
        climate=climate
),
    time.column = "age",
    interpolation.interval = 0.2
)</pre>
```

palaeodata

Dataframe with pollen and climate data.

Description

A dataframe with a regular time grid of $0.2\,\mathrm{ky}$ resolution resulting from applying mergePalaeoData to the datasets climate and pollen:

Usage

```
data(palaeodata)
```

Format

dataframe with 10 columns and 7986 rows.

Details

- age in ky before present (ky BP).
- pinus pollen counts of Pinus.
- quercus pollen counts of Quercus.
- poaceae pollen counts of Poaceae.
- artemisia pollen counts of Artemisia.
- temperatureAverage average annual temperature in Celsius degrees.

palaeodataLagged 11

- rainfallAverage average annual precipitation in milimetres per day (mm/day).
- temperature Warmest Month average temperature of the warmest month, in Celsius degrees.
- temperatureColdestMonth average temperature of the coldest month, in Celsius degrees.
- *oxigenIsotope* delta O18, global ratio of stable isotopes in the sea floor, see http://lorraine-lisiecki.com/stack.html for further details.

Author(s)

Blas M. Benito

blasbenito@gmail.com>

palaeodataLagged

Lagged data generated by prepareLaggedData.

Description

A dataframe resulting from the application of prepareLaggedData to the dataset palaeodata. The dataframe columns are:

Usage

data(palaeodataLagged)

Format

dataframe with 13 columns and 3988 rows.

Details

- Response_0 numeric, values of the response variable selected by the user in the argument response of the function prepareLaggedData. This column is used as response variable by the function computeMemory. In this case, Response represent pollen counts of Pinus.
- Response_0.2-1 numeric, time delayed values of the response for different lags (in ky). Considered together these columns represent the endogenous ecological memory.
- *climate.temperatureAverage_0* numeric, values of the variable temperatureAverage for the lag 0 (no lag). This column represents the concurrent effect of the temperature over the response. #'
- *climate.rainfallAverage_0* numeric, values of the variable rainfallAverage for the lag 0 (no lag). This column represents the concurrent effect of rainfall over the response.
- *climate.temperatureAverage_0.2-1* numeric, time delayed values of temperatureAverage for lags 0.2 to 1 (in ky). #'
- *climate.rainfallAverage_0.2-1* numeric, time delayed values of rainfallAverage for lags 0.2 to 1 (in ky).

Blas M. Benito

blasbenito@gmail.com>

12 palaeodataMemory

palaeodataMemory

Output of computeMemory

Description

List containing the output of computeMemory applied to palaeodataLagged. Its slots are:

Usage

data(palaeodataMemory)

Format

List with four slots.

Details

- memory dataframe with five columns:
 - Variable character, names and lags of the different variables used to model ecological memory.
 - median numeric, median importance across repetitions of the given Variable according to Random Forest.
 - sd numeric, standard deviation of the importance values of the given Variable across repetitions.
 - min and max numeric, percentiles 0.05 and 0.95 of importance values of the given Variable across repetitions.
- R2 vector, values of pseudo R-squared value obtained for the Random Forest model fitted on each repetition. Pseudo R-squared is the Pearson correlation between the observed and predicted data.
- prediction dataframe, with the same columns as the dataframe in the slot memory, with the median and confidence intervals of the predictions of all random forest models fitted.
- multicollinearity multicollinearity analysis on the input data performed with vif. A vif value higher than 5 indicates that the given variable is highly correlated with other variables.

plotExperiment 13

plotExperiment

Plots the output of runExperiment.

Description

It takes the output of runExperiment, and generates plots of ecological memory patterns for a large number of simulated pollen curves.

Usage

```
plotExperiment(
experiment.output = NULL,
parameters.file = NULL,
experiment.title = NULL,
sampling.names = NULL,
legend.position = "bottom",
R2 = NULL
filename = NULL,
strip.text.size = 12,
axis.x.text.size = 8,
axis.y.text.size = 12,
axis.x.title.size = 14,
axis.y.title.size = 14,
title.size = 18,
caption = ""
)
```

Arguments

```
experiment.output
                  list, output of runExperiment.
parameters.file
                  dataframe of simulation parameters.
experiment.title
                  character string, title of the plot.
sampling. names vector of character strings with the names of the columns used in the argument
                  simulations.file of runExperiment. If NULL, no pdf plot is produced.
legend.position
                  legend position in ggplot object. One of "bottom", "right", "none".
R2
                  boolean. If TRUE, pseudo R-squared values are printed along with the traits of
                  the virtual taxa.
                  character string, path and name (without extension) of the output pdf file.
filename
strip.text.size
                  size of the facet's labels.
axis.x.text.size
                  size of the labels in x axis.
```

plotInteraction

```
axis.y.text.size
size of the labels in y axis.

axis.x.title.size
size of the title of the x axis.

axis.y.title.size
size of the title of the y axis.

title.size
size of the plot title.

caption
character string, caption of the output figure.
```

Value

A ggplot2 object.

Author(s)

Blas M. Benito

blasbenito@gmail.com>

See Also

plotMemory, runExperiment

plotInteraction

Plots response surfaces for tree-based models.

Description

Plots a response surface plot or interaction plot (2 predictors and a model response) for models of the functions ranger, randomForest, and rpart. It also plots the observed data on top of the predicted surface.

Usage

```
plotInteraction(
  model = NULL,
  data = NULL,
  x = NULL,
  y = NULL,
  z = NULL,
  grid = 100,
  point.size.range = c(0.1, 1)
)
```

plotMemory 15

Arguments

model	a model object produced by the functions ranger, randomForest, or rpart.		
data	dataframe used to fit the model.		
X	character string, name of column in data to be plotted in the x axis.		
у	character string, name of column in data to be plotted in the y axis.		
Z	character string, name of column in data to be plotted as a surface. Generally, the name of the response variable in model.		
grid	numeric, resolution of the x and y axes.		
point.size.range			
	numeric vector with two values defining the range size of the points representing		

Value

A ggplot object.

Author(s)

Blas M. Benito

blasbenito@gmail.com>

the observed data.

plotMemory

Plots output of computeMemory

Description

Plots the ecological memory pattern yielded by computeMemory.

Usage

```
plotMemory(
  memory.output = NULL,
  title = "Ecological memory pattern",
  legend.position = "right",
  filename = NULL
)
```

Arguments

memory.output a dataframe with one time series per column.

title character string, name of the numeric column to be used as response in the

model.

legend.position

character vector, names of the numeric columns to be used as predictors in the

model.

filename character string, name of output pdf file. If NULL or empty, no pdf is produced.

It shouldn't include the extension of the output file.

pollen pollen

Value

A ggplot object.

pollen

Dataframe with pollen counts.

Description

A dataframe with the following columns:

Usage

```
data(pollen)
```

Format

dataframe with 5 columns and 639 rows.

Details

- age in kiloyears before present (ky BP).
- pinus pollen counts of Pinus.
- quercus pollen counts of Quercus.
- poaceae pollen counts of Poaceae.
- artemisia pollen counts of Artemisia.

Author(s)

Blas M. Benito

blasbenito@gmail.com>

prepareLaggedData 17

prepareLaggedData

Organizes time series data into lags.

Description

Takes a multivariate time series, where at least one variable is meant to be used as a response while the others are meant to be used as predictors in a model, and organizes it in time lags, generating one new column per lag and variable in the model.

Usage

```
prepareLaggedData(
  input.data = NULL,
  response = NULL,
  drivers = NULL,
  time = NULL,
  oldest.sample = "first",
  lags = NULL,
  time.zoom = NULL,
  scale = FALSE
)
```

Arguments

input.data a dataframe with one time series per column.

response character string, name of the numeric column to be used as response in the

model.

drivers character vector, names of the numeric columns to be used as predictors in the

model.

time character vector, name of the numeric column with the time/age.

oldest.sample character string, either "first" or "last". When "first", the first row taken as the

oldest case of the time series and the last row is taken as the newest case, so ecological memory flows from the first to the last row of input.data. When "last", the last row is taken as the oldest sample, and this is the mode that should be used when input.data represents a palaeoecological dataset. Default behavior

is "first".

lags numeric vector of positive integers, lags to be used in the equation. Generally, a

regular sequence of numbers, in the same units as time. The use seq to define it is highly recommended. If 0 is absent from lags, it is added automatically to allow the consideration of a concurrent effect. Lags should take into account the temporal resolution of the data, and be aligned to it. For example, if the interval between consecutive samples is 100 years, lags should be something like 0, 100, 200, 300. Lags can also be multiples of the time resolution, such

as 0, 200, 400, 600 (in the case time resolution is 100 years).

time.zoom numeric vector of two numbers of the time column used to subset the data if

desired.

18 runExperiment

scale

boolean, if TRUE, applies the scale function to normalize the data. Required if the lagged data is going to be used to fit linear models.

Details

The function interprets the time column as an index representing the

Value

A dataframe with columns representing time-delayed values of the drivers and the response. Column names have the lag number as a suffix. The response variable is identified in the output as "Response_0".

Author(s)

Blas M. Benito

blasbenito@gmail.com>

#adding lags
lagged.data <- prepareLaggedData(
   input.data = palaeodata,
   response = "pollen.pinus",
   drivers = c("climate.temperatureAverage", "climate.rainfallAverage"),
   time = "age",
   oldest.sample = "last",
   lags = seq(0.2, 1, by=0.2),
   time.zoom=NULL,
   scale=FALSE
)
str(lagged.data)</pre>
```

runExperiment

Computes ecological memory patterns on simulated pollen curves produced by the virtualPollen library.

Description

Applies computeMemory to assess ecological memory on a large set of virtual pollen curves.

runExperiment 19

Usage

```
runExperiment(
  simulations.file = NULL,
  selected.rows = 1,
  selected.columns = 1,
  parameters.file = NULL,
  parameters.names = NULL,
  sampling.names = NULL,
  driver.column = NULL,
  response.column = "Response_0",
  subset.response = "none",
  time.column = "Time",
  time.zoom = NULL,
  lags = NULL,
  repetitions = 10
)
```

Arguments

simulations.file

list of dataframes, output of the function simulatePopulation of the virtualPollen library.

selected.rows numeric vector, rows (virtual taxa) of simulations.file to be analyzed.

selected.columns

 $numeric.vector,\ columns\ (experiment\ treatments)\ of\ simulations. file\ to\ be\ analyzed.$

parameters.file

dataframe of simulation parameters.

parameters.names

vector of character strings with names of traits and niche features from parameters.file to be included in the analysis (i.e. c("maximum.age", "fecundity", "niche.A.mean", "niche.A.sd"))

sampling.names vector of character strings with the names of the columns of simulations.file.

driver.column vector of character strings, names of the columns to be considered as drivers (generally, one of "Suitability", "Driver.A", "Driver.B).

response.column

character string defining the response variable, typically "Response_0".

subset.response

character string, one of "up", "down" or "none", triggers the subsetting of the input dataset. "up" only models ecological memory on cases where the response's trend is positive, "down" selectes cases with negative trends, and "none" selects all cases.

time.column character string, name of the time/age column. Usually, "Time".

time.zoom numeric vector with two numbers defining the time/age extremes of the time interval of interest.

20 runExperiment

lags

ags numeric vector of positive integers, lags to be used in the equation. Generally, a regular sequence of numbers, in the same units as time. The use seq to define it is highly recommended. If 0 is absent from lags, it is added automatically to allow the consideration of a concurrent effect. Lags should take into account the temporal resolution of the data, and be aligned to it. For example, if the interval between consecutive samples is 100 years, lags should be something like 0, 100, 200, 300. Lags can also be multiples of the time resolution, such as 0, 200, 400, 600 (in the case time resolution is 100 years).

repetitions

integer, number of random forest models to fit.

Value

A list with 2 slots:

- names matrix of character strings, with as many rows and columns as simulations.file. Each cell holds a simulation name to be used afterwards, when plotting the results of the ecological memory analysis.
- output a list with as many columns and columns as simulations. file. Each slot holds a an output of computeMemory.
 - memory dataframe with five columns:
 - * Variable character, names and lags of the different variables used to model ecological memory.
 - * median numeric, median importance across repetitions of the given Variable according to Random Forest.
 - * sd numeric, standard deviation of the importance values of the given Variable across repetitions.
 - \ast min and max numeric, percentiles 0.05 and 0.95 of importance values of the given Variable across repetitions.
 - R2 vector, values of pseudo R-squared value obtained for the Random Forest model fitted on each repetition. Pseudo R-squared is the Pearson correlation beteween the observed and predicted data.
 - prediction dataframe, with the same columns as the dataframe in the slot memory, with the median and confidence intervals of the predictions of all random forest models fitted.
 - multicollinearity multicollinearity analysis on the input data performed with vif. A
 vif value higher than 5 indicates that the given variable is highly correlated with other
 variables.
