# Package 'GET'

August 17, 2022

Version 0.3-1 Date 2022-8-16

Title Global Envelopes

**Encoding** UTF-8

Maintainer Mari Myllymäki <mari.myllymaki@luke.fi>

Imports cluster, ggplot2, gridExtra, parallel, stats, utils, viridisLite

**Suggests** crayon, geoR, gstat, sp, fda, fda.usc, locfit, mvtnorm, patchwork, spatstat.geom, spatstat.core, spatstat.linnet, spatstat (>= 2.0-0), testthat, R.rsp

Description Implementation of global envelopes for a set of general d-dimensional vectors T in various applications. A 100(1-alpha)% global envelope is a band bounded by two vectors such that the probability that T falls outside this envelope in any of the d points is equal to alpha. Global means that the probability is controlled simultaneously for all the d elements of the vectors. The global envelopes can be used for graphical Monte Carlo and permutation tests where the test statistic is a multivariate vector or function (e.g. goodness-of-fit testing for point patterns and random sets, functional analysis of variance, functional general linear model, n-sample test of correspondence of distribution functions), for central regions of functional or multivariate data (e.g. outlier detection, functional boxplot) and for global confidence and prediction bands (e.g. confidence band in polynomial regression, Bayesian posterior prediction). GET-	package Global Envelopes	

# Description

The GET package provides implementation of global envelopes for a set of general d-dimensional vectors T in various applications. A 100(1-alpha) the probability that T falls outside this envelope in any of the d points is equal to alpha. Global means that the probability is controlled simultaneously for all the d elements of the vectors. The global envelopes can be used for central regions of functional or multivariate data (e.g. outlier detection, functional boxplot), for graphical Monte Carlo and permutation tests where the test statistic is a multivariate vector or function (e.g. goodness-of-fit testing for point patterns and random sets, functional ANOVA, functional GLM, n-sample test of correspondence of distribution functions), and for global confidence and prediction bands (e.g. confidence band in polynomial regression, Bayesian posterior prediction).

### **Details**

The **GET** package provides central regions (i.e. global envelopes) and global envelope tests with intrinsic graphical interpretation. The central regions can be constructed from (functional) data. The tests are Monte Carlo or permutation tests, which demand simulations from the tested null model. The methods are applicable for any multivariate vector data and functional data (after discretization).

To get an overview of the package, start R and type library("GET") and vignette("GET").

To get examples of point pattern analysis, start R and type library ("GET") and vignette ("pointpatterns").

### **Key functions in GET**

- *Central regions* or *global envelopes* or *confidence bands*: central\_region. E.g. 50% central region of growth curves of girls growth.
  - First create a curve\_set of the growth curves, e.g.
     cset <- create\_curve\_set(list(r = as.numeric(row.names(growth\$hgtf)), obs
     = growth\$hgtf))</pre>
  - Then calculate 50% central region (see central\_region for further arguments)
     cr <- central\_region(cset, coverage = 0.5)</li>
  - Plot the result (see plot.global\_envelope for plotting options)plot(cr)

It is also possible to do combined central regions for several sets of curves provided in a list for the function, see examples in central\_region.

• *Global envelope tests*: global\_envelope\_test is the main function. E.g. A test of complete spatial randomness (CSR) for a point pattern X:

X <- spruces # an example pattern from spatstat

- Use the function envelope of spatstat to create nsim simulations under CSR and to calculate the functions you want (below K-functions by Kest). Important: use the option 'savefuns=TRUE' and specify the number of simulations nsim.
  env <- envelope(X, nsim=999, savefuns = TRUE, fun = Kest, simulate = expression(runifpoint(ex = X)))</p>
- Perform the test (see global\_envelope\_test for further arguments)
   res <- global\_envelope\_test(env)</li>
- Plot the result (see plot.global\_envelope for plotting options)
   plot(res)

It is also possible to do combined global envelope tests for several sets of curves provided in a list for the function, see examples in global\_envelope\_test.

- Functional ordering: central\_region and global\_envelope\_test are based on different measures for ordering the functions (or vectors) from the most extreme to the least extreme ones. The core functionality of calculating the measures is in the function forder, which can be used to obtain different measures for sets of curves. Usually there is no need to call forder directly.
- Functional boxplots: fBoxplot
- Adjusted global envelope tests for composite null hypotheses

- GET. composite, see a detailed example in saplings
- One-way functional ANOVA:
  - Graphical functional ANOVA tests: graph.fanova
  - Global rank envelope based on F-values: frank.fanova
- Functional general linear model (GLM):
  - *Graphical* functional GLM: graph.flm
  - Global rank envelope based on F-values: frank.flm
  - For large data (not fitting comfortably in memory): partial\_forder
- Functional clustering: fclustering
- Functions for performing global envelopes for specific purposes:
  - Graphical n sample test of correspondence of distribution functions: GET.necdf
  - Permutation-based tests of independence to samples from any bivariate distribution:
    - \* based on cumulative distribution function GET.cdf
    - \* in a 2D contingency table GET.contingency
    - \* based on the smoothed Q-Q plot GET.qq
  - Testing global and local dependence of point patterns on covariates: GET. spatialF
  - Testing local correlations: GET.localcor
  - Variogram and residual variogram with global envelopes: GET. variogram
- Deviation tests (for simple hypothesis): deviation\_test (no graphical interpretation)
- Most functions accept the curves provided in a curve\_set object. Use create\_curve\_set to create a curve\_set object from the functions. Other formats to provide the curves to the above functions are also accepted, see the information on the help pages.

See the help files of the functions for examples.

### Workflow for (single hypothesis) tests based on single functions

To perform a test you always first need to obtain the test function T(r) for your data  $(T_1(r))$  and for each simulation  $(T_2(r), \ldots, T_{s+1}(r))$  in one way or another. Given the set of the functions  $T_i(r)$ ,  $i=1,\ldots,s+1$ , you can perform a test by global\_envelope\_test.

- 1) The workflow when using your own programs for simulations:
  - (Fit the model and) Create s simulations from the (fitted) null model.
  - Calculate the functions  $T_1(r), T_2(r), \ldots, T_{s+1}(r)$ .
  - Use create\_curve\_set to create a curve\_set object from the functions  $T_i(r), i=1,\ldots,s+1$ .
  - Perform the test

```
res <- global_envelope_test(curve_set)
where curve_set is the 'curve_set'-object you created, and plot the result
plot(res)</pre>
```

2) The workflow utilizing **spatstat**: start R, type library("GET") and vignette("pointpatterns"), which explains the workflow and gives many examples of point pattern analysis

# Functions for modifying sets of functions

It is possible to modify the curve set  $T_1(r), T_2(r), \dots, T_{s+1}(r)$  for the test.

- You can choose the interval of distances  $[r_{\min}, r_{\max}]$  by crop\_curves.
- For better visualisation, you can take  $T(r)-T_0(r)$  by residual. Here  $T_0(r)$  is the expectation of T(r) under the null hypothesis.

# Example data (see references on the help pages of each data set)

- abide\_9002\_23: see help page
- adult\_trees: a point pattern of adult rees
- cgec: centred government expenditure centralization (GEC) ratios (see graph. fanova)
- fallen\_trees: a point pattern of fallen trees
- GDPtax: GDP per capita with country groups and other covariates
- imageset3: a simulated set of images
- rimov: water temperature curves in 365 days of the 36 years
- saplings: a point pattern of saplings (see GET.composite)

The data sets are used to show examples of the functions of the library.

### **Number of functions**

If the number of functions is low, the choice of the measure (or type or depth) playes a role, as explained in vignette("GET") (Section 2.4).

Note that the recommended minimum number of simulations for the rank envelope test (Myllymäki et al., 2017) based on a single function in spatial statistics is nsim=2499. When the number of argument values is large, also larger number simulations is needed in order to have a narrow p-interval. The "erl", "cont", "area", "qdir" and "st" global envelope tests and deviation tests can be used with a lower number of simulations, although the Monte Carlo error is obviously larger with a lower number of simulations. For increasing the number of simulations, all the global rank envelopes approach the same curves.

Mrkvička et al. (2017) discussed the number of simulations for tests based on many functions.

#### **Documentation**

Myllymäki and Mrkvička (2020) provides description of the package. The material can also be found in the corresponding vignette, which is available by starting R and typing library("GET") and vignette("GET").

In the special case of spatial processes (spatial point processes, random sets), the functions are typically estimators of summary functions. The package supports the use of the R package **spatstat** for generating simulations and calculating estimators of the chosen summary function, but alternatively these can be done by any other way, thus allowing for any user-specified models/functions. To see examples of global envelopes for analysing point pattern data, start R, type library("GET") and vignette("pointpatterns").

Type citation("GET") to get a full list of references.

### Acknowledgements

Mikko Kuronen has made substantial contributions of code. Additional contributions and suggestions from Jiří Dvořák, Pavel Grabarnik, Ute Hahn, Michael Rost and Henri Seijo.

abide\_9002\_23

Local brain activity at resting state

### Description

Imaging measurements for local brain activity at resting state

### Usage

data("abide\_9002\_23")

#### **Format**

A list of the curve\_set containing the data, coordinates (x,y) where the data have been observed (third dimension is 23), the discrete factor Group (1=Autism; 2=Control), the discrete factor Sex (1=Male; 2=Female), and the continuous factor Age.

### **Details**

The data are a small part of ABIDE fALFF data available at ABIDE: http://fcon\_1000.projects.nitrc.org/indi/abide/fALFF: http://fcp-indi.github.io/docs/user/alff.html and distributed under the CC BY-NC-SA 3.0 license, https://creativecommons.org/licenses/by-nc-sa/3.0/.

The data are fractional Amplitude of Low Frequency Fluctuations (fALFF) (Zou et al. 2008) for Autism Brain Imaging Data Exchange collected resting state functional magnetic resonance imaging (R-fMRI) datasets (Di Martino et al. 2013). This data set in **GET** contains only a tiny part of the whole brain, namely the region 9002 (the right Cerebelum Crus 1) at slice 23 (see Figure 2 in Mrkvicka et al., 2019) for 514 individuals with the autism spectrum disorder (ASD) and 557 typical controls (TC) as specified in the given Group variable. Further the sex and age of each subject is given.

adult\_trees 9

adult\_trees

Adult trees data set

# **Description**

Adult trees data set

### Usage

```
data("adult_trees")
```

### **Format**

A data.frame containing the locations (x- and y-coordinates) of 67 trees in an area of 75 m  $\times$  75 m.

### **Details**

A pattern of large trees (height > 25 m) originating from an uneven aged multi-species broadleaf nonmanaged forest in Kaluzhskie Zaseki, Russia.

The pattern is a sample part of data collected over 10 ha plot as a part of a research program headed by project leader Prof. O.V. Smirnova.

central\_region

Central region / Global envelope

### **Description**

Provides central regions or global envelopes or confidence bands

# Usage

```
central_region(
  curve_sets,
  type = "erl",
  coverage = 0.5,
  alternative = c("two.sided", "less", "greater"),
  probs = c(0.25, 0.75),
  quantile.type = 7,
  central = "median",
  nstep = 2,
  ...
)
```

### **Arguments**

curve\_sets A curve\_set object or a list of curve\_set objects.

type The type of the global envelope with current options for 'rank', 'erl', 'cont',

'area', 'qdir', 'st' and 'unscaled'. See details.

coverage A number between 0 and 1. The 100\*coverage% central region will be calcu-

lated. A vector of values can also be provided, leading to the corresponding

number of central regions.

alternative A character string specifying the alternative hypothesis. Must be one of the

following: "two.sided" (default), "less" or "greater". The last two options only

available for types 'rank', 'erl', 'cont' and 'area'.

probs A two-element vector containing the lower and upper quantiles for the measure

'q' or 'qdir', in that order and on the interval [0, 1]. The default values are 0.025

and 0.975, suggested by Myllymäki et al. (2015, 2017).

quantile.type As type argument of quantile, how to calculate quantiles for 'q' or 'qdir'.

central Either "mean" or "median". If the curve sets do not contain the component theo

for the theoretical central function, then the central function (used for plotting only) is calculated either as the mean or median of functions provided in the curve sets. For 'qdir', 'st' and 'unscaled' only the mean is allowed as an option,

due to their definition.

nstep 1 or 2 for how to contruct a combined global envelope if list of curve sets is

provided. 2 (default) for a two-step combining procedure, 1 for one-step.

... Ignored.

#### **Details**

Given a curve\_set (see create\_curve\_set for how to create such an object) or an envelope object of **spatstat** or fdata object of **fda.usc**, the function central\_region construcst a central region, i.e. a global envelope, from the given set of functions (or vectors).

Generally an envelope is a band bounded by the vectors (or functions)  $T_{low}$  and  $T_{hi}$ . A  $100(1-\alpha)\%$  or 100\*coverage% global envelope is a set  $(T_{low}, T_{hi})$  of envelope vectors such that the probability that  $T_i$  falls outside this envelope in any of the d points of the vector  $T_i$  is less or equal to  $\alpha$ . The global envelopes can be constructed based on different measures that order the functions from the most extreme one to the least extreme one. We use such orderings of the functions for which we are able to construct global envelopes with intrinsic graphical interpretation.

The type of the global envelope can be chosen with the argument type and the options are given in the following. Further information about the measures, on which the global envelopes are based, can be found in Myllymäki and Mrkvička (2020, Section 2.).

- 'rank': The global rank envelope proposed by Myllymäki et al. (2017) based on the extreme rank defined as the minimum of pointwise ranks.
- 'erl': The global rank envelope based on the extreme rank length (Myllymäki et al.,2017, Mrkvička et al., 2018). This envelope is constructed as the convex hull of the functions which have extreme rank length measure that is larger or equal to the critical  $\alpha$  level of the extreme rank length measure.
- 'cont': The global rank envelope based on the continuous rank (Hahn, 2015; Mrkvička et al., 2019) based on minimum of continuous pointwise ranks. It is contructed as the convex hull in a similar way as the 'erl' envelope.
- 'area': The global rank envelope based on the area rank (Mrkvička et al., 2019) which is based on area between continuous pointwise ranks and minimum pointwise ranks for those argument (r) values for which pointwise ranks achieve the minimum (it is a combination of erl and cont). It is contructed as the convex hull in a similar way as the 'erl' and 'area' envelopes.
- 'qdir': The directional quantile envelope based on the directional quantile maximum absolute deviation (MAD) test (Myllymäki et al., 2017, 2015), which takes into account the unequal variances of the test function T(r) for different distances r and is also protected against asymmetry of distribution of T(r).
- 'st': The studentised envelope based on the studentised MAD measure (Myllymäki et al., 2017, 2015), which takes into account the unequal variances of the test function T(r) for different distances r.
- 'unscaled': The unscaled envelope (Ripley, 1981), which leads to envelopes with constant width. It corresponds to the classical maximum deviation test without scaling. This test suffers from unequal variance of T(r) over the distances r and from the asymmetry of distribution of T(r). We recommend to use the other alternatives instead. This unscaled global envelope is provided for reference.

The values of the chosen measure M are determined for each curve in the curve\_set, and based on the chosen measure, the central region, i.e. the global envelope, is constructed for the given curves.

If a list of (suitable) objects are provided in the argument curve\_sets, then by default (nstep = 2) the two-step combining procedure is used to construct the combined global envelope as described in Myllymäki and Mrkvička (2020, Section 2.2.). If nstep = 1 and the lengths of the multivariate

vectors in each component of the list are equal, then the one-step combining procedure is used where the functions are concatenated together into a one long vector (see again Myllymäki and Mrkvička, 2020, Section 2.2.).

#### Value

Either an object of class global\_envelope and or an combined\_global\_envelope object. The former class is obtained when a set of curves is provided, while the latter in the case that curve\_sets is a list of objects. The print and plot function are defined for the returned objects (see examples).

The global\_envelope object is essentially a data frame containing columns

- r =the vector of values of the argument r at which the test was made
- lo = the lower envelope based on the simulated functions; in case of a vector of coverage values, several 'lo' exist with names paste0("lo.", 100\*coverage)
- hi = the upper envelope based on the simulated functions; in case of a vector of coverage values, several 'lo' exist with names paste0("hi.", 100\*coverage)
- central = If the curve\_set (or envelope object) contains a theoretical curve, then this function is used as the central curve and returned in this component. Otherwise, the central curve is the mean or median (according to the argument central) of the test functions T\_i(r), i=2, ..., s+1. Used for visualization only.

and potentially additionally

• obs = the data function, if there is only one data function in the given curve\_sets. Otherwise not existing.

(Most often central\_region is directly applied to functional data where all curves are observed.) Additionally, the returned object has some attributes, where

- M = A vector of the values of the chosen measure for all the function. If there is only one observed function, then M[1] gives the value of the measure for this.
- M\_alpha = The critical value of M corresponding to the 100(1-alpha)% global envelope (see Myllymäki and Mrkvička, 2020, Definition 1.1. IGI).

Further the object has some attributes for printing and plotting purposes, where alternative, type, ties, alpha correspond to those in the function call and method gives a name for the method. Attributes of an object res can be obtained using the function attr, e.g. attr(res, "M") for the values of the ordering measure.

If the given set of curves had the class envelope of **spatstat**, then the returned global\_envelope object has also the class fv of spatstat, whereby one can utilize also the plotting functions of **spatstat**, see example in plot.global\_envelope. However, the envelope objects are most often used with global\_envelope\_test and not with central\_region. For an fv object, also some further attributes exists as required by fv of **spatstat**.

The combined\_global\_envelope is a list of global\_envelope objects, where the components correspond to the components of curve\_sets. The combined\_global\_envelope object constructed with nstep = 2 contains, in addition to some conventional ones (method, alternative, type, alpha, M, M\_alpha, see above), the second level envelope information as the attributes

• level2\_ge = The second level envelope on which the envelope construction is based

• level2\_curve\_set = The second level curve\_set from which level2\_ge is constructed

In the case that the given curve sets are two-dimensional, i.e., their arguments values are two-dimensional, then the returned objects have in addition to the class global\_envelope or combined\_global\_envelope, the class global\_envelope2d or combined\_global\_envelope2d, respectively. This class is assigned for plotting purposes: For the 2d envelopes, also the default plots are 2d. Otherwise the 1d and 2d objects are similar.

cgec

Centred government expenditure centralization ratios

### **Description**

Centred government expenditure centralization (GEC) ratios

### **Usage**

```
data("cgec")
```

cgec 15

#### **Format**

A list of two components. The first one is the curve\_set object containing the observed values of centred GEC observed in year 1995-2016 for the above countries. The second component group gives the grouping.

#### **Details**

The data includes the government expenditure centralization (GEC) ratio in percent that has been centred with respect to country average in order to remove the differences in absolute values of GEC. The GEC ratio is the ratio of central government expenditure to the total general government expenditure. Data were collected from the Eurostat (2018) database. Only those European countries were included, where the data were available from 1995 to 2016 without interruption. Finally, 29 countries were classified into three groups in the following way:

- Group 1: Countries joining EC between 1958 and 1986 (Belgium, Denmark, France, Germany (until 1990 former territory of the FRG), Greece, Ireland, Italy, Luxembourg, Netherlands, Portugal, Spain, United Kingdom. These countries have long history of European integration, representing the core of integration process.
- Group 2: Countries joining the EU in 1995 (Austria, Sweden, Finland) and 2004 (Malta, Cyprus), except CEEC (separate group), plus highly economically integrated non-EU countries, EFTA members (Norway, Switzerland). Countries in this group have been, or in some case even still are standing apart from the integration mainstream. Their level of economic integration is however very high.
- Group 3: Central and Eastern European Countries (CEEC), having similar features in political end economic history. The process of economic and political integration have been initiated by political changes in 1990s. CEEC joined the EU in 2004 and 2007 (Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovakia, Slovenia, data for Croatia joining in 2013 are incomplete, therefore not included).

This grouping is used in examples.

combined\_scaled\_MAD\_envelope\_test

Combined global scaled maximum absolute difference (MAD) envelope tests

### **Description**

Given a list of 'curve\_set' objects (see create\_curve\_set), a combined global scaled (directional quantile or studentized) MAD envelope test is performed with the test functions saved in the curve set objects. Details of this combined test can be found in Mrkvicka et al. (2017). The implementation of this test is provided here for historical reasons: we recommend now instead the use of global\_envelope\_test also for combined tests; these combined tests are there implemented as described in Myllymäki and Mrkvička (2020).

# Usage

```
combined_scaled_MAD_envelope_test(
  curve_sets,
  type = c("qdir", "st"),
  alpha = 0.05,
  probs = c(0.025, 0.975),
  central = "mean",
  ...
)
```

### **Arguments**

curve_sets	A curve_set (see create_curve_set) or an envelope object of <b>spatstat</b> containing a data function and simulated functions. If an envelope object is given, it must contain the summary functions from the simulated patterns which can be achieved by setting savefuns = TRUE when calling the envelope function. Alternatively, a list of curve_set or envelope objects can be given.
type	Either "qdir" for the direction quantile envelope test or "st" for the studentized envelope test.
alpha	The significance level. The 100(1-alpha)% global envelope will be calculated. If a vector of values is provided, the global envelopes are calculated for each value.
probs	A two-element vector containing the lower and upper quantiles for the measure 'q' or 'qdir', in that order and on the interval [0, 1]. The default values are 0.025 and 0.975, suggested by Myllymäki et al. (2015, 2017).

central

Either "mean" or "median". If the curve sets do not contain the component theo for the theoretical central function, then the central function (used for plotting only) is calculated either as the mean or median of functions provided in the curve sets. For 'qdir', 'st' and 'unscaled' only the mean is allowed as an option, due to their definition.

... Additional parameters to be passed to central\_region.

              type="qdir")
 plot(res)
}
```

create\_curve\_set

Create a curve\_set object

### Description

Create a curve\_set object out of a list in the right form.

### Usage

```
create_curve_set(curve_set, ...)
```

### **Arguments**

curve\_set A list containing the element obs, and optionally the elements r, sim\_m and theo. See details.

For expert use only.

#### **Details**

The function is used to clump together the functional data in the form that can be handled by the other **GET** functions (forder, central\_region, global\_envelope\_test etc.). The function create\_curve\_set takes care of checking the content of the data, and saves relevant information of the curves for global envelope methods to be used in particular for plotting the results with graphical interpretation.

obs must be either

- a vector containing the data function/vector, or
- a matrix containing the s data functions/vectors, in which case it is assumed that each column corresponds to a data function/vector.

create\_image\_set 19

If given, r describes the 1- or 2-dimensional argument values where the functions/vectors have been observed (or simulated). It must be either

- · a vector.
- a data.frame with columns "x", "y", "width" and "height", where the width and height give the width and height of the pixels placed at x and y, or
- a data.frame with columns "xmin", "xmax", "ymin" and "ymax" giving the corner coordinates of the pixels where the data have been observed.

If obs is a vector, sim\_m must be a matrix containing the simulated functions. Each column is assumed to correspond to a function, and the number of rows must match the length of obs. If obs is a matrix, sim\_m is ignored.

If obs is a vector, theo can be given and it should then correspond to a theoretical function (e.g., under the null hypothesis). If present, its length must match the length of obs.

#### Value

An object of class curve\_set containing the data. If the argument values are two-dimensional, then the curve\_set is additionally a curve\_set2d object.

### See Also

```
plot.curve_set, plot.curve_set2d
```

### **Examples**

create\_image\_set

Create a curve set of images

# **Description**

Create a curve set consisting of a set of images, given a list containing the values of the 2d functions in the right form. Only 2d functions in a rectangular windows are supported; the values are provided in matrices (arrays). For more general 2d functions see create\_curve\_set.

# Usage

```
create_image_set(image_set, ...)
```

20 crop\_curves

### **Arguments**

image\_set

A list containing elements r, obs, sim\_m and theo. r, sim\_m and theo are optional, obs needs to be provided always. If provided, r must be a list describing the argument values where the images have been observed (or simulated). It must consist of the following two or four components: a) "x" and "y" giving the equally spaced argument values for the x- and y-coordinates (first and second dimension of the 2d functions) where the data have been observed, b) "x", "y", "width" and "height", where the width and height give the width and height of the pixels placed at x and y, or c) "xmin", "xmax", "ymin" and "ymax" giving the corner coordinates of the pixels where the data have been observed. If not given, r is set to be a list of values from 1 to the number of first/second dimension of 2d functions in obs. obs must be either a 2d matrix (dimensions matching the lengths of r vectors) or 3d array containing the observed 2d functions (the third dimension matching the number of functions). If obs is a 3d array, then sim\_m is ignored. If obs is a 2d array, then sim\_m must be a 3d array containing the simulated images (2d functions) (the third dimension matching the number of functions). If included, theo corresponds to the theoretical function (e.g., under the null hypothesis) and its dimensions must either match the dimensions of 2d functions in obs or it must be a constant.

Do not use. (For internal use only.)

#### Value

The given list as a curve\_set.

# **Examples**

crop\_curves

Crop the curves to a certain interval

# **Description**

Crop the curves to a certain interval

deviation\_test 21

### Usage

```
crop_curves(curve_set, r_min = NULL, r_max = NULL)
```

### **Arguments**

curve_set	A curve_set (see create_curve_set) or an envelope object of <b>spatstat</b> . If an envelope object is given, it must contain the summary functions from the simulated patterns which can be achieved by setting savefuns = TRUE when calling the envelope function.
r_min	The minimum radius to include.
r_max	The maximum radius to include.

# **Details**

The curves can be cropped to a certain interval defined by the arguments r\_min and r\_max. The interval should generally be chosen carefully for classical deviation tests.

### Value

A curve\_set object containing the cropped summary functions and the cropped radius vector.

# **Description**

Crop the curve set to the interval of distances [r\_min, r\_max], calculate residuals, scale the residuals and perform a deviation test with a chosen deviation measure. The deviation tests are well known in spatial statistics; in **GET** they are provided for comparative purposes. Some (maximum type) of the deviation test have their corresponding envelope tests available, see Myllymäki et al., 2017 (and 'unscaled', 'st' and 'qdir' in global\_envelope\_test).

# Usage

```
deviation_test(
   curve_set,
   r_min = NULL,
   r_max = NULL,
   use_theo = TRUE,
   scaling = "qdir",
   measure = "max",
   savedevs = FALSE
)
```

22 deviation\_test

### **Arguments**

A residual curve\_set object. Can be obtained by using residual(). curve\_set The minimum radius to include. r\_min The maximum radius to include. r\_max Whether to use the theoretical summary function or the mean of the functions in use\_theo the curve set. scaling The name of the scaling to use. Options include 'none', 'q', 'qdir' and 'st'. 'qdir' is default. The deviation measure to use. Default is 'max'. Must be one of the following: measure 'max', 'int' or 'int2'. savedevs Logical. Should the global rank values k\_i, i=1,...,nsim+1 be returned? Default: FALSE.

### **Details**

The deviation test is based on a test function T(r) and it works as follows:

1) The test function estimated for the data,  $T_1(r)$ , and for nsim simulations from the null model,  $T_2(r), ...., T_{nsim+1}(r)$ , must be saved in 'curve\_set' and given to the deviation\_test function.

- 2) The deviation test function then
  - Crops the functions to the chosen range of distances  $[r_{\min}, r_{\max}]$ .
  - If the curve\_set does not consist of residuals (see residual), then the residuals  $d_i(r) = T_i(r) T_0(r)$  are calculated, where  $T_0(r)$  is the expectation of T(r) under the null hypothesis. If use\_theo = TRUE, the theoretical value given in the curve\_set\$theo is used for as  $T_0(r)$ , if it is given. Otherwise,  $T_0(r)$  is estimated by the mean of  $T_j(r)$ , j = 2, ..., nsim + 1.
  - Scales the residuals. Options are
    - 'none' No scaling. Nothing done.
    - 'q' Quantile scaling.
    - 'qdir' Directional quantile scaling.
    - 'st' Studentised scaling.

See for details Myllymäki et al. (2013).

- Calculates the global deviation measure  $u_i$ , i = 1, ..., nsim + 1, see options for 'measure'.
  - 'max' is the maximum deviation measure

$$u_i = \max_{r \in [r_{\min}, r_{\max}]} |w(r)(T_i(r) - T_0(r))|$$

- 'int2' is the integral deviation measure

$$u_i = \int_{r_{\min}}^{r_{\max}} (w(r)(T_i(r) - T_0(r)))^2 dr$$

- 'int' is the 'absolute' integral deviation measure

$$u_i = \int_{r_{\text{min}}}^{r_{\text{max}}} |w(r)(T_i(r) - T_0(r))| dr$$

fallen\_trees 23

• Calculates the p-value.

Currently, there is no special way to take care of the same values of  $T_i(r)$  occurring possibly for small distances. Thus, it is preferable to exclude from the test the very small distances r for which ties occur.

### Value

If 'savedevs=FALSE' (default), the p-value is returned. If 'savedevs=TRUE', then a list containing the p-value and calculated deviation measures  $u_i$ , i=1,...,nsim+1 (where  $u_1$  corresponds to the data pattern) is returned.

}</pre>
```

fallen\_trees

Fallen trees

# **Description**

Fallen trees

# Usage

```
data("fallen_trees")
```

24 fBoxplot

### **Format**

A list of two data frames, where trees contains the locations (x and y coordinates) and heights (=marks) of 232 trees in a window with polygonal boundary, and window species the polygonal window (see examples).

#### **Details**

The dataset comprised the locations and heights of 232 trees, which fell during two large wind gusts (1967 and 1990) in the west of France (Pontailler et al., 1997). The study area was a biological reserve, which had been preserved for at least four centuries, with little human influence for a long period (Guinier, 1950). Thus, the forest stand followed almost natural dynamics. It was an unevenaged beech stand with a few old oaks.

The data was analysed in Myllymäki et al. (2017, Supplementary material).

```

fBoxplot

Functional boxplot

### Description

Functional boxplot based on central region computed by a specified measure. The options of the measures can be found in central\_region.

# Usage

```
fBoxplot(curve_sets, factor = 1.5, coverage = 0.5, ...)
```

fclustering 25

### **Arguments**

curve\_sets A curve\_set object or a list of curve\_set objects.

The constant factor to inflate the central region to produce a functional boxplot and determine fences for outliers. Default is 1.5 as in a classical boxplot.

Coverage A number between 0 and 1. The 100\*coverage% central region will be calculated. A vector of values can also be provided, leading to the corresponding number of central regions.

Additional parameters to be passed to central\_region, which is responsible for calculating the central region (global envelope) on which the functional boxplot is based.

### **Examples**

fclustering

Functional clustering

# **Description**

Functional clustering based on a specified measure. The options of the measures can be found in central\_region.

### Usage

```
fclustering(curve_sets, k, type = c("area", "st", "erl", "cont"), ...)
```

# **Arguments**

curve\_sets

A curve\_set object or a list of curve\_set objects to which the functional clustering is to be applied. If list of curve\_set objects is provided, then the joined functional clustering is applied, which provides an equal weight combination of curve\_set objects, if the curve\_set objects contain the same numbers of elements (same lengths of vector r).

26 fclustering

k The number of clusters.

type The measure which is used to compute the dissimilarity matrix. The preferred

options are "area" and "st", but "erl" and "cont" can be also used with

caution.

... Additional parameters to be passed to central\_region, which is responsible

for calculating the central region (global envelope) on which the functional clus-

tering is based.

### **Details**

Functional clustering joins the list of curve\_set objects in one curve\_set with long functions and applies on the differences of all functions the specified measure. This provides a dissimilarity matrix which is used in partitioning around medoids procedure. The resulting clusters can then be shown by plotting the function respectively for each curve\_set. Thus for each curve\_set, the panel with all the medoids is shown followed by all clusters represented by central region, medoid and all curves belonging to it, when the result object is plotted.

If there are less than three curves in some of the groups, then the central region is not plotted. This leads to a warning message from ggplot2.

### Value

An object having the class fclust, containing

- curve\_sets = The set(s) of functions determined for clustering
- k = Number of clusters
- type = Type of clustering method
- triangineq = The proportion of combinations of functions which satisfies the triangular inequality. The triangular inequality must hold to ensure the chosen measure forms a metric. In some weird cases it does not hold for 'area' measure, therefore this check is provided to ensure the data forms metric with the 'area' measure. The triangineq must be 1 to ensure the inequality holds for all functions.
- dis = The joined dissimilarity matrix
- pam = Results of the partitioning around medoids (pam) method applied on the joined functions with the dissimilarity matrix (dis). See pam.

fdr\_envelope

The FDR envelope

# Description

Calculate the FDR envelope based on the ATSE or IATSE algorithm of Mrkvička and Myllymäki (2022).

28 fdr\_envelope

### Usage

```
fdr_envelope(
  curve_sets,
  alpha = 0.05,
  alternative = c("two.sided", "less", "greater"),
  algorithm = c("IATSE", "ATSE"),
  lower = NULL,
  upper = NULL
)
```

### **Arguments**

curve\_sets A curve\_set (see create\_curve\_set) or an envelope object of spatstat containing the observed function and the functions from which the envelope is to be constructed. Alternatively, a list of appropriate objects can be given. The significance level. The 100(1-alpha)% global envelope will be calculated. alpha If a vector of values is provided, the global envelopes are calculated for each value. alternative A character string specifying the alternative hypothesis. Must be one of the following: "two.sided" (default), "less" or "greater". The last two options only available for types 'rank', 'erl', 'cont' and 'area'. algorithm Either "IATSE" or "ATSE" standing for the iteratively adaptive two-stage envelope and the adaptive two-stage envelope, respectively, see Mrkvička and Myllymäki (2022). A single number (or a vector of suitable length) giving a lower bound for the lower functions. Used only for the extension, see Mrkvička and Myllymäki (2022, p.

A single number (or a vector of suitable length) giving an upper bound for the upper

functions.

Functional ordering

# Description

Calculates different measures for ordering the functions (or vectors) from the most extreme to least extreme one

# Usage

```
forder(
  curve_sets,
  measure = "erl",
  scaling = "qdir",
  alternative = c("two.sided", "less", "greater"),
  use_theo = TRUE,
  probs = c(0.025, 0.975),
  quantile.type = 7
)
```

### **Arguments**

curve_sets	A curve_set object or a list of curve_set objects.
measure	The measure to use to order the functions from the most extreme to the least extreme one. Must be one of the following: 'rank', 'erl', 'cont', 'area', 'max', 'int', 'int2'. Default is 'erl'.
scaling	The name of the scaling to use if measure is 'max', 'int' or 'int2'. Options include 'none', 'q', 'qdir' and 'st', where 'qdir' is the default.
alternative	A character string specifying the alternative hypothesis. Must be one of the following: "two.sided" (default), "less" or "greater". The last two options only available for types 'rank', 'erl', 'cont' and 'area'.
use_theo	Logical. When calculating the measures 'max', 'int', 'int2', should the theoretical function from curve_set be used (if 'theo' provided), see deviation_test.
probs	A two-element vector containing the lower and upper quantiles for the measure 'q' or 'qdir', in that order and on the interval [0, 1]. The default values are 0.025 and 0.975, suggested by Myllymäki et al. (2015, 2017).
quantile.type	As type argument of quantile, how to calculate quantiles for 'q' or 'qdir'.

# **Details**

Given a curve\_set (see create\_curve\_set for how to create such an object) or an envelope object of **spatstat**, which contains curves  $T_1(r), \ldots, T_s(r)$ , the functions are ordered from the most extreme one to the least extreme one by one of the following measures (specified by the argument measure). Note that 'erl', 'cont' and 'area' were proposed as a refinement to the extreme ranks 'rank', because the extreme ranks can contain many ties. All of these completely non-parametric measures are smallest for the most extreme functions and largest for the least extreme

30 forder

ones, whereas the deviation measures ('max', 'int' and 'int2') obtain largest values for the most extreme functions.

- 'rank': extreme rank (Myllymäki et al., 2017). The extreme rank  $R_i$  is defined as the minimum of pointwise ranks of the curve  $T_i(r)$ , where the pointwise rank is the rank of the value of the curve for a specific r-value among the corresponding values of the s other curves such that the lowest ranks correspond to the most extreme values of the curves. How the pointwise ranks are determined exactly depends on the whether a one-sided (alternative is "less" or "greater") or the two-sided test (alternative="two.sided") is chosen.
- 'erl': extreme rank length (Myllymäki et al., 2017). Considering the vector of pointwise ordered ranks  $\mathbf{R}_i$  of the ith curve, the extreme rank length measure  $R_i^{erl}$  is equal to

$$R_i^{erl} = \frac{1}{s} \sum_{j=1}^s \mathbf{1}(\mathbf{R}_j" < "\mathbf{R}_i)$$

where  $\mathbf{R}_j$ " < " $\mathbf{R}_i$  if and only if there exists  $n \leq d$  such that for the first k, k < n, pointwise ordered ranks of  $\mathbf{R}_j$  and  $\mathbf{R}_i$  are equal and the n'th rank of  $\mathbf{R}_j$  is smaller than that of  $\mathbf{R}_i$ . The scaling by

S

is applied to normalize the ranks following Mrkvička et al. (2019) and Narisetty and Nair (2016).

- 'cont': continuous rank (Hahn, 2015; Mrkvička et al., 2019) based on minimum of continuous pointwise ranks
- 'area': area rank (Mrkvička et al., 2019) based on area between continuous pointwise ranks and minimum pointwise ranks for those argument (r) values for which pointwise ranks achieve the minimum (it is a combination of erl and cont)
- 'max' and 'int' and 'int2': Further options for the measure argument that can be used together with scaling. See the help in deviation\_test for these options of measure and scaling. These measures are largest for the most extreme functions and smallest for the least extreme ones. The arguments use\_theo and probs are relevant for these measures only (otherwise ignored).

For details see Myllymäki and Mrkvička et al. (2020, Section 2)

# Value

A vector containing one of the above mentioned measures k for each of the functions in the curve set. If the component obs in the curve set is a vector, then its measure will be the first component (named 'obs') in the returned vector.

frank.fanova

Rank envelope F-test

# **Description**

A one-way functional ANOVA based on the rank envelope applied to F values

32 frank.fanova

### Usage

```
frank.fanova(
   nsim,
   curve_set,
   groups,
   typeone = c("fwer", "fdr"),
   variances = "equal",
   test.equality = c("mean", "var", "cov"),
   cov.lag = 1,
   savefuns = FALSE,
   ...
)
```

### **Arguments**

nsim The number of random permutations.

curve\_set The original data (an array of functions) provided as a curve\_set object (see

create\_curve\_set) or a fdata object (see fdata). The curve set should include
the argument values for the functions in the component r, and the observed

functions in the component obs.

groups The original groups (a factor vector representing the assignment to groups).

typeone Character string indicating which type I error rate to control, either the fami-

lywise error rate ('fwer') or false discovery rate ('fdr'). Further arguments to the FWER or FDR envelope can be passed in argument GET.args. If 'fwer', the type of the envelope can be chosen by specifying the argument type in

GET.args.

variances Either "equal" or "unequal". If "equal", then the traditional F-values are used.

If "unequal", then the corrected F-values are used. The current implementation

uses 1m to get the corrected F-values.

A character with possible values mean (default), var and cov. If mean, the functional ANOVA is performed to compare the means in the groups. If var, then the equality of variances of the curves in the groups is tested by performing the

graphical functional ANOVA test on the functions

$$Z_{ij}(r) = T_{ij}(r) - \bar{T}_j(r).$$

If cov, then the equality of lag cov.lag covariance is tested by performing the fANOVA with

$$W_{ij}(r) = \sqrt{|V_{ij}(r)| \cdot sign(V_{ij}(r))},$$

where

$$V_{ij}(r) = (T_{ij}(r) - \bar{T}_j(r))((T_{ij}(r+s) - \bar{T}_j(r+s))).$$

See Mrkvicka et al. (2020) for more details.

cov.lag The lag of the covariance for testing the equality of covariances, see test.equality.

savefuns Logical. If TRUE, then the functions from permutations are saved to the attribute simfuns.

... Additional parameters to be passed to global\_envelope\_test (if typeone = "fwer") or fdr\_envelope (if typeone = "fdr").

frank.flm 33

### **Details**

The test assumes that there are J groups which contain  $n_1, \ldots, n_J$  functions  $T_{ij}, i = \ldots, J, j = 1, \ldots, n_j$ . The functions should be given in the argument x, and the groups in the argument groups. The test assumes that there exists non random functions  $\mu(r)$  and  $\mu_i(r)$  such that

$$T_{ij}(r) = \mu(r) + \mu_i(r) + e_{ij}(r), i = 1, \dots, J, j = 1, \dots, n_j$$

where  $e_{ij}(r)$  are independent and normally distributed. The test vector is

$$\mathbf{T} = (F(r_1), F(r_2), \dots, F(r_K)),$$

where  $F(r_i)$  stands for the F-statistic. The simulations are performed by permuting the test functions. Further details can be found in Mrkvička et al. (2020).

The argument variances="equal" means that equal variances across groups are assumed. The correction for unequal variances can be done by using the corrected F-statistic (option variances="unequal").

Unfortunately this test is not able to detect which groups are different from each other.

# **Examples**

frank.flm

F rank functional GLM

# Description

Multiple testing in permutation inference for the general linear model (GLM)

34 frank.flm

# Usage

```
frank.flm(
  nsim,
  formula.full,
  formula.reduced,
  typeone = c("fwer", "fdr"),
  curve_sets,
  factors = NULL,
  savefuns = TRUE,
  lm.args = NULL,
  GET.args = NULL,
  mc.cores = 1,
  mc.args = NULL,
  cl = NULL,
  method = c("best", "simple", "mlm", "complex", "lm")
)
```

### **Arguments**

nsim The number of random permutations.

formula.full The formula specifying the general linear model, see formula in lm.

formula.reduced

The formula of the reduced model with nuisance factors only. This model should

be nested within the full model.

typeone Character string indicating which type I error rate to control, either the fami-

lywise error rate ('fwer') or false discovery rate ('fdr'). Further arguments to the FWER or FDR envelope can be passed in argument GET.args. If 'fwer', the type of the envelope can be chosen by specifying the argument type in

GET.args.

curve\_sets A named list of sets of curves giving the dependent variable (Y), and possibly

additionally factors whose values vary across the argument values of the functions. The dimensions of the elements should match with each other. Note that factors that are fixed across the functions can be given in the argument factors.

Also fdata objects allowed.

factors A data frame of factors. An alternative way to specify factors when they are

constant for all argument values of the functions. The number of rows of the data frame should be equal to the number of curves. Each column should specify

the values of a factor.

savefuns Logical or "return". If TRUE, then the functions from permutations are saved to

the attribute simfuns. If "return", then the function returns the permutations in a curve\_set, instead of the result of the envelope test on those; this can be used by

partial\_forder.

1m. args A named list of additional arguments to be passed to 1m. See details.

GET.args A named list of additional arguments to be passed to global\_envelope\_test.

mc.cores The number of cores to use, i.e. at most how many child processes will be run

simultaneously. Must be at least one, and parallelization requires at least two

cores. On a Windows computer mc.cores must be 1 (no parallelization). For details, see mclapply, for which the argument is passed. Parallelization can be used in generating simulations and in calculating the second stage tests.

mc.args A named list of additional arguments to be passed to mclapply. Only relevant

if mc. cores is more than 1.

cl Allows parallelization through the use of parLapply (works also in Windows),

see the argument cl there, and examples.

method For advanced use.

### **Details**

The function frank.flm performs a nonparametric test of significance of a covariate in the functional GLM. Similarly as in the graphical functional GLM (graph.flm), the Freedman-Lane algorithm (Freedman and Lane, 1983) is applied to permute the functions (to obtain the simulations under the null hypothesis of "no effects"); consequently, the test achieves the desired significance level only approximately. If the reduced model contains only a constant, then the algorithm corresponds to simple permutation of raw data. In contrast to the graphical functional GLM, the F rank functional GLM is based on the F-statistics that are calculated at each argument value of the functions. The global envelope test is applied to the observed and simulated F-statistics. The test is able to find if the factor of interest is significant and also which argument values of the functional domain are responsible for the potential rejection.

The specification of the full and reduced formulas is important. The reduced model should be nested within the full model. The full model should include in addition to the reduced model the interesting factors whose effects are under investigation.

There are different versions of the implementation depending on the application.

- If all the covariates are constant across the functions, i.e. they can be provided in the argument factors, and there are no extra arguments given by the user in lm.args, then a fast implementation is used to directly compute the F-statistics.
- If all the covariates are constant across the functions, but there are some extra arguments, then a linear model is fitted separately by least-squares estimation to the data at each argument value of the functions fitting a multiple linear model by 1m. The possible extra arguments passed in 1m.args to 1m must be of the form that 1m accepts for fitting a multiple linear model. In the basic case, no extra arguments are needed.
- If some of the covariates vary across the space, i.e. they are provided in the list of curve sets in the argument curve\_sets together with the dependent functions, but there are no extra arguments given by the user in lm. args, there is a rather fast implementation of the F-value calculation (which does not use lm).
- If some of the covariates vary across the space and there are user specified extra arguments given in lm.args, then the implementation fits a linear model at each argument value of the functions using lm, which can be rather slow. The arguments lm.args are passed to lm for fitting each linear model.

By default the fastest applicable method is used. This can be changed by setting method argument. The cases above correspond to "simple", "mlm", "complex" and "lm". Changing the default can be useful for checking the validity of the implementation.

36 GDPtax

### Value

A global\_envelope object, which can be printed and plotted directly.

**GDPtax** 

GDP per capita with country groups and profit tax

# **Description**

GDP per capita with country groups and profit tax

# Usage

```
data("GDPtax")
```

GDPtax 37

#### **Format**

A list of a three components. The first one (GDP) is a curve\_set object with components r and obs containing the years of observations and the GDP curves, i.e. the observed values of GDP in those years. Each column of obs contains the GDP for the years for a particular country (seen as column names). The country grouping is given in the list component Group and the profit tax in Profittax.

#### **Details**

The data includes the GDP per capita (current US\$) for years 1980-2017 (World Bank national accounts data, and OECD National Accounts data files). The data have been downloaded from the webpage https://datamarket.com/data/set/15c9/gdp-per-capita-current-us#!ds=15c9!hd1&display=line, distributed under the CC-BY 4.0 (https://datacatalog.worldbank.org/public-licenses#cc-by). From the same webpage the profit tax in 2010 (World Bank, Doing Business Project (http://www.doingbusiness.org/ExploreTopics/and Total tax rate ( were downloaded. Furthermore, different country groups were formed from countries for which the GDP was available for 1980-2017 and profit tax for 2010:

- Group 1 (Major Advanced Economies (G7)): "Canada", "France", "Germany", "Italy", Japan"
- Group 2 (Euro Area excluding G7): "Austria", "Belgium", "Cyprus", "Finland", "Greece", "Ireland", "Luxembourg", "Netherlands", "Portugal", "Spain"
- Group 3 (Other Advanced Economies (Advanced Economies excluding G7 and Euro Area)): "Australia", "Denmark", "Iceland", "Norway", "Sweden", "Switzerland"
- Group 4 (Emerging and Developing Asia): "Bangladesh", "Bhutan", "China", "Fiji", "India", "Indonesia", "Malaysia", "Nepal", "Philippines", "Thailand", "Vanuatu"

Test of independence based on cumulative distribution function

## **Description**

Permutation-based test of independence in a bivariate vector using the empirical joint cumulative distribution function as the test statistic.

## Usage

```
GET.cdf(X, ngrid = c(20, 20), nsim = 999, seq.x = NULL, seq.y = NULL, ...)
```

### **Arguments**

X	A matrix with n rows and 2 columns. Each row contains one bivariate observation.
ngrid	Vector with two elements, giving the number of grid points to be used in the test statistic for each of the two marginals. The default is 20 in each marginal.
nsim	The number of random permutations used.
seq.x	For the first marginal, the values at which the empirical cumulative distribution function will be evaluated. If NULL (the default), sequence of quantiles will be used, equidistant in terms of probability.
seq.y	For the second marginal, the values at which the empirical cumulative distribution function will be evaluated. If NULL (the default), sequence of quantiles will be used, equidistant in terms of probability.
	Additional parameters to be passed to global_envelope_test. In particularly, alpha specifies the nominal significance level of the test, and type the type of the global envelope test.

### **Details**

Permutation-based test of independence in a bivariate sample, based on empirical joint cumulative distribution function computed on a grid of ngrid[1] times ngrid[2] arguments. The grid points are chosen according to the quantiles of the marginal distributions.

If the observed data are the pairs  $\{(X_1, Y_1), \dots, (X_n, Y_n)\}$ , the permutations are obtained by randomly permuting the values in the second marginal, i.e.  $\{(X_1, Y_{\pi(1)}), \dots, (X_n, Y_{\pi(n)})\}$ .

The test itself is performed using the global envelope test of the chosen version, see the argument type of global\_envelope\_test.

 MrkvickaEtal2017 = FALSE,
  mc.cores = 1L
)
```

#### **Arguments**

Χ An object containing the data in some form. A curve\_set (see create\_curve\_set) or an envelope object (of the **spatstat** package), as the curve\_sets argument of global\_envelope\_test (need to provide X.ls), or a fitted point process model of spatstat (e.g. object of class ppm or kppm), or a point pattern object of class ppp of **spatstat**, or another data object (need to provide simfun, fitfun, calcfun). X.ls A list of objects as curve\_sets argument of global\_envelope\_test, giving the second stage simulations, see details. The number of simulations to be generated in the primary test. Ignored if X.1s nsim provided. Number of simulations in each basic test. There will be nsim repetitions of nsimsub the basic test, each involving nsimsub simulated realisations. Total number of simulations will be nsim \* (nsimsub + 1). simfun A function for generating simulations from the null model. If given, this function is called by replicate(n=nsim, simfun(simfun.arg), simplify=FALSE) to make nsim simulations. Here simfun.arg is obtained by fitfun(X). fitfun A function for estimating the parameters of the null model. The function should return the fitted model in the form that it can be directly passed to simfun as its argument. calcfun A function for calculating a summary function from a simulation of the model. The default is the identity function, i.e. the simulations from the model are functions themselves. The use of calcfun is still experimental. Preferably provide X and X.1s instead, if X is not a point pattern or fitted point process model object of spatstat. testfuns A list of lists of parameters to be passed to the envelope function of **spatstat** if X is a point pattern of a fitted point process model of **spatstat**. A list of parameters should be provided for each test function that is to be used in the combined test. Additional parameters to the envelope function of **spatstat** in the case where only one test function is used. In that case, this is an alternative to providing the parameters in the argument testfuns. If envelope is also used to generate simulations under the null hypothesis (if simfun not provided), then also recall to specify how to generate the simulations. The type of the global envelope with current options for 'rank', 'erl', 'cont', type 'area', 'qdir', 'st' and 'unscaled'. See details. alpha The significance level. The 100(1-alpha)% global envelope will be calculated. If a vector of values is provided, the global envelopes are calculated for each value. alternative A character string specifying the alternative hypothesis. Must be one of the following: "two.sided" (default), "less" or "greater". The last two options only available for types 'rank', 'erl', 'cont' and 'area'. probs A two-element vector containing the lower and upper quantiles for the measure

'q' or 'qdir', in that order and on the interval [0, 1]. The default values are 0.025

and 0.975, suggested by Myllymäki et al. (2015, 2017).

r\_min The minimum argument value to include in the test.

r\_max The maximum argument value to include in the test. in calculating functions by

the envelope function of spatstat.

take\_residual Logical. If TRUE (needed for visual reasons only) the mean of the simulated

functions is reduced from the functions in each first and second stage test.

save.cons.envelope

Logical flag indicating whether to save the unadjusted envelope test results.

savefuns Logical flag indicating whether to save all the simulated function values. Similar

to the same argument of the envelope function of **spatstat**.

verbose Logical flag indicating whether to print progress reports during the simulations.

Similar to the same argument of envelope function of **spatstat**.

MrkvickaEtal2017

Logical. If TRUE, type is "st" or "qdir" and several test functions are used, then the combined scaled MAD envelope presented in Mrkvička et al. (2017) is calculated. Otherwise, the two-step procedure described in global\_envelope\_test is used for combining the tests. Default to FALSE. The option is kept for histor-

ical reasons.

mc.cores The number of cores to use, i.e. at most how many child processes will be run

simultaneously. Must be at least one, and parallelization requires at least two cores. On a Windows computer mc.cores must be 1 (no parallelization). For details, see mclapply, for which the argument is passed. Parallelization can be

used in generating simulations and in calculating the second stage tests.

#### Details

The specification of X, X.ls, fitfun, simfun is important:

- If X.1s is provided, then the global envelope test is calculated based on functions in these objects. X should be a curve\_set (see create\_curve\_set) or an envelope object of spatstat including the observed function and simulations from the tested model. X.1s should be a list of curve\_set or envelope (of R package spatstat) objects, where each component contains an "observed" function f that has been simulated from the model fitted to the data and the simulations that have been obtained from the same model that has been fitted to the "observed" f. The user has the responsibility that the functions have been generated correctly, the test is done based on these provided simulations. See the examples.
- Otherwise, if simfun and fitfun are provided, X can be general. The function fitfun is used for fitting the desired model M and the function simfun for simulating from a fitted model M. These functions should be coupled with each other such that the object returned by fitfun is directly accepted as the (single) argument in simfun. In the case, that the global envelope should not be calculated directly for X (X is not a function), calcfun can be used to specify how to calculate the function from X and from simulations generated by simfun. Special attention is needed in the correct specification of the functions, see examples.
- Otherwise, X should be either a fitted (point process) model object or a ppp object of the R package **spatstat**.
  - If X is a fitted (point process) model object of the R package spatstat, then the simulations from this model are generated and summary functions for testing calculated by the

envelope function of **spatstat**. Which summary function to use and how to calculate it, can be passed to envelope either in . . . or testfuns. Unless otherwise specified the default function of envelope, i.g. the K-function, is used. The argument testfuns should be used to specify the test functions in the case where one wants to base the test on several test functions.

- If X is a ppp object of **spatstat**, then the envelope function is used for simulations and model fitting and the complete spatial randomness (CSR) is tested (with intensity parameter).

For the rank envelope test, the global envelope test is the test described in Myllymäki et al. (2017) with the adjustment of Baddeley et al. (2017). For other test types, the test (also) uses the two-stage procedure of Dao and Genton (2014) with the adjustment of Baddeley et al. (2017) as describbed in Myllymäki and Mrkvička (2020).

See examples also in saplings.

#### Value

An object of class global\_envelope or combined\_global\_envelope, which can be printed and plotted directly. See global\_envelope\_test.

GET.contingency 45

### **Description**

Permutation-based test of independence in a 2D contingency table, using the matrix of observed counts as the test statistic.

### Usage

```
GET.contingency(X, nsim = 999, ...)
```

## Arguments

A matrix with n rows and 2 columns. Each row contains one bivariate observation.

The number of random permutations used.

Additional parameters to be passed to global\_envelope\_test. In particularly, alpha specifies the nominal significance level of the test, and type the type of the global envelope test.

#### **Details**

Permutation-based test of independence in a 2D contingency table, using the matrix of observed counts as the test statistic.

If the observed data are the pairs  $\{(X_1, Y_1), \dots, (X_n, Y_n)\}$ , the permutations are obtained by randomly permuting the values in the second marginal, i.e.  $\{(X_1, Y_{\pi(1)}), \dots, (X_n, Y_{\pi(n)})\}$ .

The test itself is performed using the global envelope test in the chosen version. Text output can be printed in the console by typing the object name. The cells in which the observed value exceeds the upper envelope printed in red, and cells in which the observed value is lower than the lower envelope printed in cyan. Standard output of the global envelope test is also returned and can be plotted or analyzed accordingly.

GET.localcor

The test of local correlations

## **Description**

The test of local correlations using Vilodomat et al. (2014) procedure for resamples and the FDR envelope of Mrkvička and Myllymäki (2022).

### Usage

```
GET.localcor(
  data,
  Delta,
  nsim = 1000,
  typeone = c("fdr", "fwer"),
  varying.bandwidth = FALSE,
  bandwidth.nn = 0.1,
  bandwidth.h = 5.281,
 maxk = 300,
  savefuns = FALSE,
 N_s = 1000,
 mc.cores = 1L,
 mc.args = NULL,
  cl = NULL,
  notest = FALSE,
)
```

# **Arguments**

data

A data frame where the first two columns correspond to the values of the two random fields, whose correlations are to be studied, and the third and fourth columns correspond to the x- and y-coordinates where these random fields have been observed. In addition, the width and height of the pixels at each (x,y) can be given in the fifth and sixth column. Warning: no checks for the data input.

Delta

A smoothing parameter of the local correlation. According to Vilodomat et al. (2014): Delta is a set of values for the proportion of neighbors to consider for the smoothing step. No default. The user may have to experiment with different values to find one suitable for their data.

nsim

The number of resamples.

typeone

Character string indicating which type I error rate to control, either the familywise error rate ('fwer') or false discovery rate ('fdr'). Further arguments to the FWER or FDR envelope can be passed in argument GET.args. If 'fwer', the type of the envelope can be chosen by specifying the argument type in

GET.args.

GET.localcor 47

varying.bandwidth

Logical, whether to use a varying bandwidth to calculate the local correlations

or not. See Vilodomat et al. (2014).

bandwidth.nn Nearest neighbor component of the smoothing parameter for varying bandwidth

to be passed to the argument nn of the function 1p of the **locfit** package. The user may have to experiment with different values to find one suitable for their data. Default set to to 0.1 according to Vilodamat et al. (2014, supporting

information).

bandwidth.h Non-varying bandwidth, to be passed to the argument h of the function 1p of

**locfit.** The user may have to experiment with different values to find one suitable for their data. Default to 5.281 according to Vilodamat et al. (2014, supporting

information).

maxk See locfit and locfit.raw of **locfit**. Default here to 300 following Vilodomat

et al. (2014).

savefuns Logical. If TRUE, then the functions from permutations are saved to the attribute

simfuns.

N\_s If the number of observations is bigger than N\_s, following Vilodomat et al.

(2014) a subsample of size N\_s is taken every time when a variogram is calcu-

lated.

mc.cores The number of cores to use, i.e. at most how many child processes will be run

simultaneously. Must be at least one, and parallelization requires at least two cores. On a Windows computer mc.cores must be 1 (no parallelization). For details, see mclapply, for which the argument is passed. Parallelization can be

used in generating simulations and in calculating the second stage tests.

mc.args A named list of additional arguments to be passed to mclapply. Only relevant

if mc. cores is more than 1.

cl Allows parallelization through the use of parLapply (works also in Windows),

see the argument cl there, and examples.

notest Logical. FALSE means that the test is done. TRUE allows to calculate only local

correlation for the data, which can be beneficial for choosing the bandwidths before running the test. If TRUE, then only the observed local correlations will

be returned.

... Additional parameters to be passed to fdr\_envelope (if typeone = "fdr") or to

global\_envelope\_test (if typeone = "fwer").

#### **Details**

The code is a modification of the supporting information code of Vilodomat et al. (2014) available at https://doi.org/10.1111/biom.12139. The modification includes the FDR (or FWER, if specified by the argument typeone) envelopes for the test of local correlations, i.e. multiple testing correction and graphical illustration of the test results.

Variograms are calculated using the package **geoR** and the local correlations using the R package **locfit**. These packages should be installed to use GET.localcor.

Currently the data is provided in the format of Vilodomat et al. (2014, Supporting information). Additionally width and height of area represented by a data point can be provided, see the argument data. This information is used for plotting purposes when plotting the output by plot().

48 GET.necdf

Examples will be provided in a vignette.

#### Value

A global envelope object (with possible additional classes), see description of main components in global\_envelope (Value). Additional attributes: p\_global contains the Monte Carlo p-value for the global test of correlation. cor\_global and cor\_global\_sim contain the value of the correlation for data and permuted data, respectively. If savefuns = TRUE, then permutations contain the permuted values of the first random field according to Viladomat et al. (2014) procedure, and cset contains all the local correlations for the data and permuted data in a curve\_set object (see create\_curve\_set).

GET.necdf

Graphical n sample test of correspondence of distribution functions

#### **Description**

Compare the distributions of two (or more) samples.

### Usage

```
GET.necdf(
    x,
    r = seq(min(unlist((lapply(x, min)))), max(unlist((lapply(x, max)))), length = 100),
    contrasts = FALSE,
    nsim,
    ...
)
```

## **Arguments**

X	A list of numeric vectors, one for each sample.
r	The sequence of argument values at which the distribution functions are to be compared. The default is 100 equally spaced values between the minimum and maximum over all groups.
contrasts	Logical. FALSE and TRUE specify the two test functions as described in description part of this help file.
nsim	The number of random permutations.
	Additional parameters to be passed to global_envelope_test (if typeone = "fwer") or fdr_envelope (if typeone = "fdr").

GET.necdf 49

#### **Details**

A global envelope test can be performed to investigate whether the n distribution functions differ from each other and how do they differ. This test is a generalization of the two-sample Kolmogorov-Smirnov test with a graphical interpretation. We assume that the observations in the sample i are an i.i.d. sample from the distribution  $F_i(r)$ ,  $i = 1, \ldots, n$ , and we want to test the hypothesis

$$F_1(r) = \ldots = F_n(r).$$

If contrasts = FALSE (default), then the test statistic is taken to be

$$\mathbf{T} = (\hat{F}_1(r), \dots, \hat{F}_n(r))$$

where  $\hat{F}_i(r) = (\hat{F}_i(r_1), \dots, \hat{F}_i(r_k))$  is the ecdf of the *i*th sample evaluated at argument values  $r = (r_1, \dots, r_k)$ . This is our recommended test function for the test. Another possibility is given by contrasts = TRUE, and then the test statistic is contructed from all pairwise differences,

$$\mathbf{T} = (\hat{F}_1(r) - \hat{F}_2(r), \hat{F}_1(r) - \hat{F}_3(r), \dots, \hat{F}_{n-1}(r) - \hat{F}_n(r))$$

The simulations under the null hypothesis that the distributions are the same are obtained by permuting the individuals of the groups. The default number of permutation, if nsim is not specified, is n\*1000 - 1 for the case contrasts = FALSE and (n\*(n-1)/2)\*1000 - 1 for the case contrasts = TRUE, where n is the length of x.

GET.qq

Test of independence based on the smoothed Q-Q plot

## Description

Permutation-based test of independence in a bivariate vector using the smoothed Q-Q plot as the test statistic.

## Usage

```
GET.qq(
    X,
    ngrid = c(64, 64),
    nsim = 999,
    sigma = NULL,
    atoms.x = NULL,
    atoms.y = NULL,
    ...
)
```

## **Arguments**

Χ	A matrix with n rows and 2 columns. Each row contains one bivariate observation.
ngrid	Vector with two elements, giving the number of grid points to be used in the test statistic for each of the two marginals. The default is 64 in each marginal.
nsim	The number of random permutations used.
sigma	Standard deviation of the smoothing kernel to be used for smoothing the Q-Q plot when computing the test statistic. If NULL, sensible default value is used based on the number of observations.
atoms.x	Vector specifying atomic values in the first marginal. See Examples.
atoms.y	Vector specifying atomic values in the second marginal. See Examples.
	Additional parameters to be passed to global_envelope_test. In particularly, alpha specifies the nominal significance level of the test, and type the type of the global envelope test.

GET.qq 51

### **Details**

Permutation-based test of independence in a bivariate sample, based on Q-Q representation and estimate of the intensity function computed on a regular grid of ngrid[1] times ngrid[2] points.

If the observed data are the pairs  $\{(X_1, Y_1), \dots, (X_n, Y_n)\}$ , the permutations are obtained by randomly permuting the values in the second marginal, i.e.  $\{(X_1, Y_{\pi(1)}), \dots, (X_n, Y_{\pi(n)})\}$ .

The test itself is performed using the global envelope test in the chosen version.

52 GET.spatialF

GET.spatialF

Testing global and local dependence of point patterns on covariates

#### Description

Compute the spatial F- and S-statistics and perform the one-stage global envelope tests proposed by Myllymäki et al. (2020).

### Usage

```
GET.spatialF(
   X,
   formula.full,
   formula.reduced,
   fitfun,
   covariates,
   nsim,
   bw = spatstat.core::bw.scott(X),
   bw.S = bw,
   dimyx = NULL,
   ...
)
```

### **Arguments**

X A ppp object of **spatstat** representing the observed point pattern.

formula.full A formula for the trend of the full model.

formula.reduced

A formula for the trend of the reduced model that is a submodel of the full

model.

fitfun A function of a point pattern, model formula and covariates, giving a fitted

model object that can be used with simulate.

covariates A list of covariates.

nsim The number of simulations.

bw The bandwidth for smoothed residuals. bw. S The radius for the local S(u)-statistic.

dimyx Pixel array dimensions for smoothed residuals. See as. mask of **spatstat**.

... Additional arguments to be passed to global\_envelope\_test.

#### Value

list with three components

- F =the global envelope test based on the F(u) statistic
- S =the global envelope test based on the S(u) statistic
- coef = the coefficients of the full model given by fitfun

(iH I	.variog	ram

Variogram and residual variogram with global envelopes

## **Description**

The function accompanies the function variogram with global envelopes that are based on permutations of the variable(s) or residuals for which the variogram is calculated. Therefore, one can inspect the hypothesis of "no spatial autocorrelation" of the variable or the residuals of the fitted model.

## Usage

```
GET.variogram(
  object,
  nsim = 999,
  data = NULL,
    ...,
  GET.args = NULL,
  savefuns = TRUE
)
```

## **Arguments**

object	An object of class gstat or a variogram. formula. In the first case, direct (residual) variograms are calculated for the variable defined in object. Only one variable allowed. In the second case, a formula defining the response vector and (possible) regressors, in case of absence of regressors, use e.g. z~1. See variogram.
nsim	The number of permutations.
data	A data frame where the names in formula are to be found. If NULL, the data are assumed to be found in the object.
	Additional parameters to be passed to variogram.
GET.args	A named list of additional arguments to be passed to global_envelope_test.
savefuns	Logical. If TRUE, then the functions from permutations are saved to the attribute simfuns.

global\_envelope\_test 55

```
# Variogram can be calculated as follows by the function variogram of the gstat package.
 # The function variogram takes a formula as its first argument:
 \# \log(zinc)^{-1} means that we assume a constant trend for the variable \log(zinc).
 lzn.vgm <- variogram(object=log(zinc)~1, data=meuse)</pre>
 plot(lzn.vgm)
 # Variogram with global envelopes is as easy:
 lzn.vgm.GET <- GET.variogram(object=log(zinc)~1, data=meuse)</pre>
 plot(lzn.vgm.GET)
 \# Instead of the constant mean, denoted by ~1, a mean function can
 # be specified, e.g. using ~sqrt(dist) as a predictor variable:
 lznr.vgm <- variogram(log(zinc)~sqrt(dist), meuse)</pre>
 # In this case, the variogram of residuals with respect
 # to a fitted mean function are shown.
 plot(lznr.vgm)
 # The variogram with global envelopes (obtained by permuting the residuals):
 lznr.vgm.GET <- GET.variogram(object=log(zinc)~sqrt(dist), data=meuse)</pre>
 plot(lznr.vgm.GET)
 # Directional variograms
 lzn.dir <- variogram(object=log(zinc)~1, data=meuse, alpha=c(0, 45, 90, 135))</pre>
 plot(lzn.dir)
 # with global envelopes
 lzn.dir.GET <- GET.variogram(object=log(zinc)~1, data=meuse, alpha=c(0, 45, 90, 135))
 plot(lzn.dir.GET)
 # Use instead gstat objects
 g <- gstat(id="ln.zinc", formula=log(zinc)~1, data=meuse)</pre>
 # or: g <- gstat(id="ln.zinc", formula=log(zinc)~sqrt(dist), data=meuse)</pre>
 # The variogram
 plot(variogram(g))
 # The variogram with global envelopes:
 g.GET <- GET.variogram(object=g)</pre>
 plot(g.GET)
}
```

global\_envelope\_test Global envelope test

#### **Description**

Global envelope test, global envelopes and p-values

### Usage

```
global_envelope_test(
```

```
curve_sets,
type = "erl",
alpha = 0.05,
alternative = c("two.sided", "less", "greater"),
ties = "erl",
probs = c(0.025, 0.975),
quantile.type = 7,
central = "mean",
nstep = 2,
...
)
```

### Arguments

curve\_sets

A curve\_set (see create\_curve\_set) or an envelope object of **spatstat** containing a data function and simulated functions. If an envelope object is given, it must contain the summary functions from the simulated patterns which can be achieved by setting savefuns = TRUE when calling the envelope function. Alternatively, a list of curve\_set or envelope objects can be given.

type

The type of the global envelope with current options for 'rank', 'erl', 'cont', 'area', 'qdir', 'st' and 'unscaled'. See details.

alpha

The significance level. The 100(1-alpha)% global envelope will be calculated. If a vector of values is provided, the global envelopes are calculated for each value.

alternative

A character string specifying the alternative hypothesis. Must be one of the following: "two.sided" (default), "less" or "greater". The last two options only available for types 'rank', 'erl', 'cont' and 'area'.

ties

The method to obtain a unique p-value when type = 'rank'. Possible values are 'midrank', 'random', 'conservative', 'liberal' and 'erl'. For 'conservative' the resulting p-value will be the highest possible. For 'liberal' the p-value will be the lowest possible. For 'random' the rank of the obs within the tied values is uniformly sampled so that the resulting p-value is at most the conservative option and at least the liberal option. For 'midrank' the mid-rank within the tied values is taken. For 'erl' the extreme rank length p-value is calculated. The default is 'erl'.

probs

A two-element vector containing the lower and upper quantiles for the measure 'q' or 'qdir', in that order and on the interval [0, 1]. The default values are 0.025 and 0.975, suggested by Myllymäki et al. (2015, 2017).

quantile.type

As type argument of quantile, how to calculate quantiles for 'q' or 'qdir'.

central

Either "mean" or "median". If the curve sets do not contain the component theo for the theoretical central function, then the central function (used for plotting only) is calculated either as the mean or median of functions provided in the curve sets. For 'qdir', 'st' and 'unscaled' only the mean is allowed as an option, due to their definition.

nstep

1 or 2 for how to contruct a combined global envelope if list of curve sets is provided. 2 (default) for a two-step combining procedure, 1 for one-step.

. . .

Additional parameters to be passed to central\_region.

#### **Details**

Given a curve\_set (see create\_curve\_set for how to create such an object) or an envelope object of **spatstat**, which contains both the data curve (or function or vector)  $T_1(r)$  (in the component obs) and the simulated curves  $T_2(r), \ldots, T_{s+1}(r)$  (in the component sim\_m), the function global\_envelope\_test performs a global envelope test. The functionality of the function is rather similar to the function central\_region, but in addition to ordering the functions from the most extreme one to the least extreme one using different measures and providing the global envelopes with intrinsic graphical interpretation, p-values are calculated for the test. Thus, while central\_region can be used to construct global envelopes in a general setting, the function global\_envelope\_test is devoted to testing as its name suggests.

The function global\_envelope\_test is the main function for global envelope tests (for simple hypotheses). Different type of global envelope tests can be performed. We use such ordering of the functions for which we are able to construct global envelopes with intrinsic graphical interpretation.

- 'rank': the completely non-parametric rank envelope test (Myllymäki et al., 2017) based on minimum of pointwise ranks
- 'erl': the completely non-parametric rank envelope test based on extreme rank lengths (Myllymäki et al., 2017; Mrkvička et al., 2018) based on number of minimal pointwise ranks
- 'cont': the completely non-parametric rank envelope test based on continuous rank (Hahn, 2015; Mrkvička et al., 2019) based on minimum of continuous pointwise ranks
- 'area': the completely non-parametric rank envelope test based on area rank (Mrkvička et al., 2019) based on area between continuous pointwise ranks and minimum pointwise ranks for those argument (r) values for which pointwise ranks achieve the minimum (it is a combination of erl and cont)
- "qdir", the directional quantile envelope test, protected against unequal variance and asymmetry of T(r) for different distances r (Myllymäki et al., 2015, 2017)
- "st", the studentised envelope test, protected against unequal variance of T(r) for different distances r (Myllymäki et al., 2015, 2017)
- "unscaled", the unscaled envelope (providing a baseline) that has a contant width and that corresponds to the classical maximum deviation test (Ripley, 1981).

The first four types are global rank envelopes. The 'rank' envelope test is a completely non-parametric test, which provides the 100(1-alpha) T(r) on the chosen interval of distances and associated p-values. The other three are modifications of 'rank' to treat the ties in the extreme rank ordering on which the 'rank' test is based on. The last three envelopes are global scaled maximum absolute difference (MAD) envelope tests. The unscaled envelope test leads to envelopes with constant width over the distances r. Thus, it suffers from unequal variance of T(r) over the distances r and from the asymmetry of distribution of T(r). We recommend to use the other global envelope tests available. The unscaled envelope is provided as a reference.

See Myllymäki and Mrkvička (2020, Section 2.), i.e. vignette("GET"), for more detailed description of the measures and the corresponding envelopes.

See vignette("pointpatterns") for examples of point pattern analyses.

#### Value

Either an object of class "global\_envelope" or "combined\_global\_envelope", similarly as the objects returned by central\_region.

The global\_envelope is essentially a data frame containing columns

- the values of the argument r at which the test was made, copied from the argument curve\_sets with the corresponding names
- obs = values of the data function, copied from the argument curve\_sets (unlike for central regions, obs always exists for a global envelope test)
- lo = the lower envelope; in case of a vector of alpha values, several 'lo' exist with names paste0("lo.", 100\*(1-alpha))
- hi = the upper envelope; in case of a vector of alpha values, several 'lo' exist with names paste0("hi.", 100\*(1-alpha))
- central = a central curve as specified in the argument central.

Moreover, the returned object has the same attributes as the global\_envelope object returned by central\_region and in addition

• p = A point estimate for the p-value (default is the mid-rank p-value).

and in the case that type = 'rank' also

- p\_interval = The p-value interval  $[p_{liberal}, p_{conservative}]$ .
- ties = As the argument ties.

The combined\_global\_envelope is a list of global\_envelope objects containing the above mentioned columns and which all together form the global envelope. It has the same attributes as described in central\_region, and in addition also the p-value p. The 2d classes are attached as described in central\_region.

### **Procedure**

- 1) First the curves are ranked from the most extreme one to the least extreme one by a measure that is specified by the argument type. The options are
  - 'rank': extreme ranks (Myllymäki et al., 2017)
  - 'erl': extreme rank lengths (Myllymäki et al., 2017; Mrkvička et al., 2018)
  - 'cont': continuous ranks (Hahn, 2015; Mrkvička et al., 2019)
  - 'area': area ranks (Mrkvička et al., 2019)
  - 'qdir': the directional quantile maximum absolute deviation (MAD) measure (Myllymäki et al., 2015, 2017)
  - 'st': the studentized MAD measure (Myllymäki et al., 2015, 2017)
  - 'unscaled': the unscaled MAD measure (Ripley, 1981)
- 2) Based on the measures used to rank the functions, the 100(1-alpha)% global envelope is provided. It corresponds to the 100\*coverage% central region.
- 3) P-values: In the case type="rank", based on the extreme ranks  $k_i$ , i=1,...,s+1, the p-interval is calculated. Because the extreme ranks contain ties, there is not just one p-value. The p-interval is given by the most liberal and the most conservative p-value estimate. Also a single p-value is calculated. By default this single p-value is the extreme rank length p-value ("erl") as specified by the argument ties. If the case of other measures, a (single) p-value based on the given ordering of the functions is calculated and returned in the attribute p.

global\_envelope\_test 59

#### **Number of simulations**

For the global "rank" envelope test, Myllymäki et al. (2017) recommended to use at least 2500 simulations for testing at the significance level alpha = 0.05 for single function tests, based on experiments with summary functions for point processes evaluated approximately at 500 argument values. In this case, the width of the p-interval associated with the extreme rank measure tended to be smaller than 0.01. The tests 'erl', 'cont' and 'area', similarly as the MAD deviation/envelope tests 'qdir', 'st' and 'unscaled', allow in principle a lower number of simulations to be used than the test based on extreme ranks ('rank'), because no ties occur for these measures. If affordable, we recommend in any case some thousands of simulations for all the measures to achieve a good power and repeatability of the test. If the dimension of the test functions is higher, also the number of simulations should preferably be higher.

### Tests based on several functions

If a list of (suitable) objects are provided in the argument curve\_sets, then by default (nstep = 2) the two-step combining procedure is used to perform the combined global test as described in Myllymäki and Mrkvička (2020). If nstep = 1 and the lengths of the multivariate vectors in each component of the list are equal, then the one-step combining procedure is used where the functions are concatenated together into a one long vector.

graph.fanova

One-way graphical functional ANOVA

## Description

One-way ANOVA tests for functional data with graphical interpretation

## Usage

```
graph.fanova(
   nsim,
   curve_set,
   groups,
   typeone = c("fwer", "fdr"),
   variances = "equal",
   contrasts = FALSE,
   n.aver = 1L,
   mirror = FALSE,
   savefuns = FALSE,
   test.equality = c("mean", "var", "cov"),
   cov.lag = 1,
   ...
)
```

### **Arguments**

nsim The number of random permutations.

curve\_set The original data (an array of functions) provided as a curve\_set object (see

create\_curve\_set) or a fdata object (see fdata). The curve set should include
the argument values for the functions in the component r, and the observed

functions in the component obs.

groups The original groups (a factor vector representing the assignment to groups).

typeone	Character string indicating which type I error rate to control, either the fami-
	lywise error rate ('fwer') or false discovery rate ('fdr'). Further arguments to
	the FWER or FDR envelope can be passed in argument GET.args. If 'fwer',
	the type of the envelope can be chosen by specifying the argument type in
	GET.args.

Either "equal" or "unequal". If "unequal", then correction for unequal variances as explained in details will be done. Only relevant for the case test.equality = "means" (default).

Logical. FALSE and TRUE specify the two test functions as described in description part of this help file.

n.aver If variances = "unequal", there is a possibility to use variances smoothed by appying moving average to the estimated sample variances. n.aver determines how many values on each side do contribute (incl. value itself).

mirror The complement of the argument circular of filter. Another parameter for the moving average to estimate sample variances (see n.aver).

savefuns Logical. If TRUE, then the functions from permutations are saved to the attribute simfuns.

A character with possible values mean (default), var and cov. If mean, the functional ANOVA is performed to compare the means in the groups. If var, then the equality of variances of the curves in the groups is tested by performing the graphical functional ANOVA test on the functions

$$Z_{ij}(r) = T_{ij}(r) - \bar{T}_j(r).$$

If cov, then the equality of lag cov.lag covariance is tested by performing the fANOVA with

$$W_{ij}(r) = \sqrt{|V_{ij}(r)| \cdot sign(V_{ij}(r))},$$

where

$$V_{ij}(r) = (T_{ij}(r) - \bar{T}_{ij}(r))((T_{ij}(r+s) - \bar{T}_{ij}(r+s))).$$

See Mrkvicka et al. (2020) for more details.

cov.lag The lag of the covariance for testing the equality of covariances, see test.equality.

Additional parameters to be passed to global\_envelope\_test (if typeone = "fwer") or fdr\_envelope (if typeone = "fdr").

### **Details**

variances

contrasts

This function can be used to perform one-way graphical functional ANOVA tests described in Mrkvička et al. (2020). Both 1d and 2d functions are allowed in curve sets.

The tests assume that there are J groups which contain  $n_1, \ldots, n_J$  functions  $T_{ij}, i = \ldots, J, j = 1, \ldots, n_j$ . The functions should be given in the argument curve\_set, and the groups in the argument groups. The tests assume that  $T_{ij}, i = 1, \ldots, n_j$  is an iid sample from a stochastic process with mean function  $\mu_j$  and covariance function  $\gamma_j(s,t)$  for s,t in R and  $j = 1, \ldots, J$ .

To test the hypothesis

$$H_0: \mu_1(r) \equiv \mu_2(r) \equiv \ldots \equiv \mu_J(r),$$

you can use the test function

$$\mathbf{T} = (\overline{T}_1(\mathbf{r}), \overline{T}_2(\mathbf{r}), \dots, \overline{T}_J(\mathbf{r}))$$

where  $\overline{T}_i(\mathbf{r})$  is a vector of mean values of functions in the group j. This test function is used when contrasts = FALSE (default).

The hypothesis can equivalently be written as

$$H_0: \mu_i(r) - \mu_j(r) = 0, i = 1, \dots, J - 1, j = 1, \dots, J.$$

and, alternatively, one can use the test function (vector) taken to consist of the differences of the group averages,

$$\mathbf{T}' = (\overline{T}_1(\mathbf{r}) - \overline{T}_2(\mathbf{r}), \overline{T}_1(\mathbf{r}) - \overline{T}_3(\mathbf{r}), \dots, \overline{T}_{J-1}(\mathbf{r}) - \overline{T}_J(\mathbf{r})).$$

The choice is available with the option contrasts = TRUE. This test corresponds to the post-hoc test done usually after an ANOVA test is significant, but it can be directed tested by means of the combined rank test (Mrkvička et al., 2017) with this test vector.

The test as such assumes that the variances are equal across the groups of functions. To deal with unequal variances, the differences are rescaled as the first step as follows

$$S_{ij}(r) = \frac{T_{ij}(r) - \overline{T}(r)}{\sqrt{Var(T_i(r))}} \sqrt{Var(T(r))} + \overline{T}(r)$$

where  $\overline{T}(\mathbf{r})$  is the overall sample mean and  $\sqrt{Var(T(r))}$  is the overall sample standard deviation. This scaling of the test functions can be obtained by giving the argument variances = "unequal".

graph.flm

graph.flm

Graphical functional GLM

### Description

Non-parametric graphical tests of significance in functional general linear model (GLM)

## Usage

```
graph.flm(
  nsim,
  formula.full,
  formula.reduced,
  typeone = c("fwer", "fdr"),
  curve_sets,
  factors = NULL,
  contrasts = FALSE,
  savefuns = FALSE,
  lm.args = NULL,
  GET.args = NULL,
 mc.cores = 1L,
 mc.args = NULL,
 c1 = NULL,
  fast = TRUE
)
```

## **Arguments**

nsim

The number of random permutations.

formula.full

The formula specifying the general linear model, see formula in lm.

formula.reduced

The formula of the reduced model with nuisance factors only. This model should be nested within the full model.

typeone

Character string indicating which type I error rate to control, either the familywise error rate ('fwer') or false discovery rate ('fdr'). Further arguments to the FWER or FDR envelope can be passed in argument GET.args. If 'fwer', the type of the envelope can be chosen by specifying the argument type in GET.args.

graph.flm 67

curve_sets	A named list of sets of curves giving the dependent variable (Y), and possibly additionally factors whose values vary across the argument values of the functions. The dimensions of the elements should match with each other. Note that factors that are fixed across the functions can be given in the argument factors. Also fdata objects allowed.
factors	A data frame of factors. An alternative way to specify factors when they are constant for all argument values of the functions. The number of rows of the data frame should be equal to the number of curves. Each column should specify the values of a factor.
contrasts	Logical. FALSE and TRUE specify the two test functions as described in description part of this help file.
savefuns	Logical. If TRUE, then the functions from permutations are saved to the attribute simfuns.
lm.args	A named list of additional arguments to be passed to 1m. See details.
GET.args	A named list of additional arguments to be passed to global_envelope_test.
mc.cores	The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and parallelization requires at least two cores. On a Windows computer mc.cores must be 1 (no parallelization). For details, see mclapply, for which the argument is passed. Parallelization can be used in generating simulations and in calculating the second stage tests.
mc.args	A named list of additional arguments to be passed to mclapply. Only relevant if mc.cores is more than 1.
cl	Allows parallelization through the use of parLapply (works also in Windows), see the argument cl there, and examples.
fast	Logical. See details.

### **Details**

The function graph. flm performs the graphical functional GLM of Mrkvička et al. (2021), described also in Section 3.6 of Myllymäki and Mrkvička (2020) (type vignette("GET") in R). This is a nonparametric graphical test of significance of a covariate in functional GLM. The test is able to find not only if the factor of interest is significant, but also which functional domain is responsible for the potential rejection. In the case of functional multi-way main effect ANOVA or functional main effect ANCOVA models, the test is able to find which groups differ (and where they differ). In the case of functional factorial ANOVA or functional factorial ANCOVA models, the test is able to find which combination of levels (which interactions) differ (and where they differ). The described tests are global envelope tests applied in the context of GLMs. The Freedman-Lane algorithm (Freedman and Lane, 1983) is applied to permute the functions (to obtain the simulations under the null hypothesis of "no effects"); consequently, the test approximately achieves the desired significance level.

The specification of the full and reduced formulas is important. The reduced model should be nested within the full model. The full model should include in addition to the reduced model the interesting factors whose effects are under investigation. The implementation to find the coefficients of the interesting factors is based on dummy.coef and the restrictions there apply.

The regression coefficients serve as test functions in the graphical functional GLM. For a continuous interesting factor, the test function is its regression coefficient across the functional domain. For

68 graph.flm

a discrete factor, there are two possibilities that are controlled by the arguments contrasts. If contrasts = FALSE, then the test statistic is the function/long vector where the coefficients related to all levels of the factor are joined together. If contrasts = TRUE, then the differences between the same coefficients are considered instead. Given the coefficients in a specific order that is obtained through the use of 1m and 1m and 1m coef, the differences are taken for couples i and j where i < j and reducing j from i (e.g. for three groups 1,2,3, the constrasts are 1-2, 1-3, 2-3).

There are different versions of the implementation depending on the application. Given that the argument fast is TRUE, then

- If all the covariates are constant across the functions, i.e. they can be provided in the argument factors, then a linear model is fitted separately by least-squares estimation to the data at each argument value of the functions fitting a multiple linear model by 1m. The possible extra arguments passed in 1m. args to 1m must be of the form that 1m accepts for fitting a multiple linear model. In the basic case, no extra arguments are needed.
- If some of the covariates vary across the space and there are user specified extra arguments given in lm.args, then the implementation fits a linear model at each argument value of the functions using lm, which can be rather slow. The arguments lm.args are passed to lm for fitting each linear model.

By setting fast = FALSE, it is possible to use the slow version for any case. Usually this is not desired.

#### Value

A global\_envelope or combined\_global\_envelope object, which can be printed and plotted directly.

imageset3

A simulated set of images

### **Description**

A simulated set of images with a categorical factor (with three levels)

### Usage

```
data("imageset3")
```

70 imageset3

#### **Format**

A list of the image\_set containing the simulated images, and the discrete group factor in the list component Group.

#### **Details**

We considered a categorical factor Group obtaining the values 0, 1 or 2 according to the group to which the image belongs to (10 images in each of the three groups). The images were simulated in the square window  $[-1,1]^2$  from the general linear model (GLM)

$$Y(r) = \exp(-10 \cdot ||r||) \cdot (1 + \mathbf{1}(g = 2)) + \epsilon(r),$$

where ||r|| denotes the Euclidean distance of the pixel to the origin, g is the group and the error stems from an inhomogeneous distribution over \$I\$ with the normal and bimodal errors in the middle and periphery of the image:

$$\epsilon(r) = \mathbf{1}(\|r\| \le 0.5)G(r) + \mathbf{1}(\|r\| > 0.5)\frac{1}{2}G(r)^{1/5},$$

where G(r) is a Gaussian random field with the exponential correlation structure with scale parameter 0.15 and standard deviation 0.2. Consequently, the first two groups (0,1) have the same mean, while a bigger bump appears in the third group (2) in the middle of the image.

is.curve\_set 71

is.curve\_set

Check class.

## Description

Check class.

## Usage

```
is.curve_set(x)
```

## Arguments

Х

An object to be checked.

partial\_forder

Functional ordering in parts

## **Description**

If the functional data doesn't comfortably fit in memory it is possible to compute functional ordering by splitting the domain of the data (voxels in a brain image), using partial\_forder on each part and finally combining the results with combine\_forder.

# Usage

```
partial_forder(
   curve_set,
   measure = c("erl", "rank", "cont", "area"),
   alternative = c("two.sided", "less", "greater"))

combine_forder(ls)
```

## **Arguments**

curve_set	A curve_set object, usually a part of a larger curve_set.
measure	The measure to use to order the functions from the most extreme to the least extreme one. Must be one of the following: 'rank', 'erl', 'cont', 'area', 'max', 'int', 'int2'. Default is 'erl'.
alternative	A character string specifying the alternative hypothesis. Must be one of the following: "two.sided" (default), "less" or "greater". The last two options only available for types 'rank', 'erl', 'cont' and 'area'.
ls	List of objects returned by partial_forder

### Value

See forder

#### **Examples**

plot.combined\_fboxplot

Plot method for the class 'combined\_fboxplot'

# Description

Plot method for the class 'combined\_fboxplot'

## Usage

```
## $3 method for class 'combined_fboxplot'
plot(
    x,
    labels,
    scales = "free",
    ncol = 2 + 1 * (length(x) == 3),
    digits = 3,
    outliers = TRUE,
    ...
)
```

### **Arguments**

x an 'combined\_fboxplot' object

labels A character vector of suitable length. If dotplot = TRUE (for the level 2 test), then labels for the tests at x-axis. Otherwise labels for the separate plots.

scales	See facet_wrap. Use scales = "free" when the scales of the functions in the global envelope vary. scales = "fixed" is a good choice, when you want the same y-axis for all components. A sensible default based on r-values exists.
ncol	The maximum number of columns for the figures. Default 2 or 3, if the length of x equals 3. (Relates to the number of curve_sets that have been combined.)
digits	The number of digits used for printing the p-value or p-interval in the default main.
outliers	Logical. If TRUE, then the functions outside the functional boxplot are drawn.
	Ignored.

```
plot.combined_global_envelope
```

Plot method for the class 'combined\_global\_envelope'

# Description

This function provides plots for combined global envelopes.

# Usage

```
## S3 method for class 'combined_global_envelope'
plot(
    x,
    labels,
    scales,
    sign.col = "red",
    ncol = 2 + 1 * (length(x) == 3),
    digits = 3,
    level = 1,
    ...
)
```

# **Arguments**

Χ	An 'combined_global_envelope' object
labels	A character vector of suitable length. If dotplot = TRUE (for the level 2 test), then labels for the tests at x-axis. Otherwise labels for the separate plots.
scales	See facet_wrap. Use scales = "free" when the scales of the functions in the global envelope vary. scales = "fixed" is a good choice, when you want the same y-axis for all components. A sensible default based on r-values exists.
sign.col	The color for the observed curve when outside the global envelope (significant regions). Default to "red". Setting the color to NULL corresponds to no coloring. If the object contains several envelopes, the coloring is done for the widest one.
ncol	The maximum number of columns for the figures. Default 2 or 3, if the length of x equals 3. (Relates to the number of curve_sets that have been combined.)

digits The number of digits used for printing the p-value or p-interval in the default main.

1 or 2. In the case of two-step combined tests (with several test functions),

two different plots are available: 1 for plotting the combined global envelopes (default and most often wanted) or 2 for plotting the second level test result.

... Ignored.

### **Details**

Plotting method for the class 'combined\_global\_envelope', i.e. combined envelopes for 1d functions.

#### See Also

```
central_region
```

```
plot.combined_global_envelope2d
```

Plotting function for combined 2d global envelopes

# **Description**

If fixedscales is FALSE (or 0) all images will have separate scale. If fixedscales is TRUE (or 1) each x[[i]] will have a common scale. If fixedscales is 2 all images will have common scale.

If more than one envelope has been calculated (corresponding to several coverage/alpha), only the largest one is plotted.

### Usage

```
## $3 method for class 'combined_global_envelope2d'
plot(
    x,
    fixedscales = 2,
    labels,
    what = c("obs", "lo", "hi", "lo.sign", "hi.sign"),
    sign.col = "red",
    transparency = 155/255,
    digits = 3,
    ...
)
```

### **Arguments**

x A 'global\_envelope' object for two-dimensional functions fixedscales 0, 1 or 2. See details.

labels A character vector of suitable length giving the labels for the separate plots. Default exists. This parameter allows replacing the default. what Character vector specifying what information should be plotted for 2d functions. A combination of: Observed ("obs"), upper envelope ("hi"), lower envelope ("lo"), observed with significantly higher values highlighted ("hi.sign"), observed with significantly lower values highlighted ("lo.sign"). sign.col The color for the observed curve when outside the global envelope (significant regions). Default to "red". Setting the color to NULL corresponds to no coloring. If the object contains several envelopes, the coloring is done for the widest one. transparency A number between 0 and 1 (default 155/255, 60 Similar to alpha of rgb. Used in plotting the significant regions for 2d functions. digits The number of digits used for printing the p-value or p-interval in the default Ignored.

```

plot.fboxplot

Plot method for the class 'fboxplot'

# Description

Plot method for the class 'fboxplot'

# Usage

```
## S3 method for class 'fboxplot'
plot(x, digits = 3, outliers = TRUE, ...)
```

78 plot.fclust

# **Arguments**

x an 'fboxplot' object
 digits The number of digits used for printing the p-value or p-interval in the default main.
 outliers Logical. If TRUE, then the functions outside the functional boxplot are drawn.
 ... Ignored.

### **Examples**

plot.fclust

Plot method for the class 'fclust'

### Description

Plot method for the 'fclust' objects returned by fclustering.

# Usage

```
## S3 method for class 'fclust'
plot(x, plotstyle = c("marginal", "joined"), coverage = 0.5, nstep, ncol, ...)
```

### **Arguments**

x An 'fclust' object.

plotstyle The resulting central regions of clusters can be plotted by sorting the appro-

priate curve\_set only 'marginal' or by sorting the joined list of curve\_set objects 'joined'. If 'joined' is used the shown central regions corresponds to the joined ordering used to cluster the functional data. If 'marginal' is used the shown central regions do not correspond to the joined ordering used to cluster the functional data, but better express the shape of cluster with respect to given

curve\_set.

coverage The coverage of central regions to be used to show the clusters.

plot.global\_envelope 79

nstep	1 or 2 for how to contruct a combined (joined) global envelope if there are more than one sets of curves. Default to 1, if the numbers of points where the curves are observed (r) are the same in each set, and 2 otherwise.
ncol	The number of columns in the graphical output, when there is just one set of curves that has been ordered. If not given, c(1, k+1) is used, which gives all plots in one row. For more sets of curves, the rows are fixed to correspond to the sets (one row for each set).
	Ignored.

### **Details**

The clusters are shown respectively for each curve\_set. Thus for each curve\_set the panel with all the medoids is shown followed by all clusters represented by central region, medoid and all curves belonging to it.

For all sources, the function plots the deepest curves for all clusters and the deepest curve of each cluster together with the desired central region and all the curves of the group.

# **Description**

Plot method for the class 'global\_envelope'

# Usage

```
## S3 method for class 'global_envelope'
plot(
    x,
    dotplot = length(x$r) < 10,
    sign.col = "red",
    labels = NULL,
    digits = 3,
    ...
)</pre>
```

### **Arguments**

X	An 'global_envelope' object
dotplot	Logical. If TRUE, then instead of envelopes a dot plot is done. Suitable for low dimensional test vectors. Default: TRUE if the dimension is less than 10, FALSE otherwise.
sign.col	The color for the observed curve when outside the global envelope (significant regions). Default to "red". Setting the color to NULL corresponds to no coloring. If the object contains several envelopes, the coloring is done for the widest one.
labels	A character vector of suitable length. If $dotplot = TRUE$ , then labels for the tests at x-axis.
digits	The number of digits used for printing the p-value or p-interval in the default main.
	Ignored.

```

plot.global\_envelope2d

Plotting function for 2d global envelopes

# **Description**

If more than one envelope has been calculated (corresponding to several coverage/alpha), only the largest one is plotted.

# Usage

```
## $3 method for class 'global_envelope2d'
plot(
    x,
    fixedscales = TRUE,
    what = c("obs", "lo", "hi", "lo.sign", "hi.sign"),
    sign.col = "red",
    transparency = 155/255,
    digits = 3,
    ...
)
```

# **Arguments**

X	A 'global_envelope' object for two-dimensional functions
fixedscales	Logical. TRUE for the same scales for all images.
what	Character vector specifying what information should be plotted for 2d functions. A combination of: Observed ("obs"), upper envelope ("hi"), lower envelope ("lo"), observed with significantly higher values highlighted ("hi.sign"), observed with significantly lower values highlighted ("lo.sign").
sign.col	The color for the observed curve when outside the global envelope (significant regions). Default to "red". Setting the color to NULL corresponds to no coloring. If the object contains several envelopes, the coloring is done for the widest one.
transparency	A number between 0 and 1 (default 155/255, 60 Similar to alpha of $\tt rgb$ . Used in plotting the significant regions for 2d functions.
digits	The number of digits used for printing the p-value or p-interval in the default main.
	Ignored.

popgrowthmillion

Population growth

### **Description**

Population growth

# Usage

```
data("popgrowthmillion")
```

#### **Format**

A matrix, where each row corresponds to a year and each column to a country. Column names correspond to the countries, and row names to the years.

#### **Details**

This dataset includes population growth, i.e. population at the end of the year divided by population at the beginning of the year, in 134 countries in years from 1950 to 2015. The dataset includes only countries over million inhabitants in 1950. The data were extracted from the supplement of Nagy et al. (2017) distributed under the GPL-2 license.

qdir\_envelope 87

qdir_envelope	Global scaled maximum absolute difference (MAD) envelope tests

#### **Description**

Performs the global scaled MAD envelope tests, either directional quantile or studentised, or the unscaled MAD envelope test. These tests correspond to calling the function global\_envelope\_test with type="qdir", type = "st" and type="unscaled", respectively. The functions qdir\_envelope, st\_envelope and unscaled\_envelope have been kept for historical reasons; preferably use global\_envelope\_test with the suitable type argument.

### Usage

```
qdir_envelope(curve_set, ...)
st_envelope(curve_set, ...)
unscaled_envelope(curve_set, ...)
```

### **Arguments**

A curve\_set (see <a href="mailto:create\_curve\_set">create\_curve\_set</a>) or an envelope object of <a href="mailto:spatstat">spatstat</a>. If an envelope object is given, it must contain the summary functions from the simulated patterns which can be achieved by setting savefuns = TRUE when calling the function of <a href="mailto:spatstat">spatstat</a>.

... Additional parameters to be passed to global\_envelope\_test.

#### **Details**

The directional quantile envelope test (Myllymäki et al., 2015, 2017) takes into account the unequal variances of the test function T(r) for different distances r and is also protected against asymmetry of T(r).

The studentised envelope test (Myllymäki et al., 2015, 2017) takes into account the unequal variances of the test function T(r) for different distances r.

The unscaled envelope test (Ripley, 1981) corresponds to the classical maximum deviation test without scaling, and leads to envelopes with constant width over the distances r. Thus, it suffers from unequal variance of T(r) over the distances r and from the asymmetry of distribution of T(r). We recommend to use the other global envelope tests available, see global\_envelope\_test for full list of alternatives.

### Value

An object of class global\_envelope of combined\_global\_envelope which can be printed and plotted directly. See global\_envelope\_test for more details.

}
```

rank\_envelope

The rank envelope test

### **Description**

The rank envelope test, p-values and global envelopes. The test corresponds to the global envelope test that can be carried out by global\_envelope\_test by specifying the type for which the options "rank", "erl", "cont" and "area" are available. The last three are modifications of the first one

rank\_envelope 89

to treat the ties in the extreme rank ordering used in "rank". This function is kept for historical reasons.

# Usage

```
rank_envelope(curve_set, type = "rank", ...)
```

### **Arguments**

curve\_set A curve\_set (see create\_curve\_set) or an envelope object of spatstat. If

an envelope object is given, it must contain the summary functions from the simulated patterns which can be achieved by setting savefuns = TRUE when

calling the function of spatstat.

type The type of the global envelope with current options for "rank", "erl", "cont"

and "area". If "rank", the global rank envelope accompanied by the p-interval is given (Myllymäki et al., 2017). If "erl", the global rank envelope based on extreme rank lengths accompanied by the extreme rank length p-value is given (Myllymäki et al., 2017, Mrkvička et al., 2018). See details and additional sec-

tions thereafter.

... Additional parameters to be passed to global\_envelope\_test.

# **Details**

The "rank" envelope test is a completely non-parametric test, which provides the 100(1-alpha)% global envelope for the chosen test function T(r) on the chosen interval of distances and associated p-values. The other three types are solutions to break the ties in the extreme ranks on which the "rank" envelope test is based on.

Note: The method to break ties for the global type = "rank" envelope (Myllymäki et al., 2017) can be done by the argument ties with default to ties = "erl" corresponding to the extreme rank length breaking of ties. In this case the global envelope corresponds to the extreme rank measure. If instead choosing type to be "erl", "cont" or "area", then the global envelope corresponds to these measures.

#### Value

An object of class global\_envelope of combined\_global\_envelope which can be printed and plotted directly. See global\_envelope\_test for more details.

### **Number of simulations**

The global "erl", "cont", "area" envelope tests allow in principle a lower number of simulations to be used than the global "rank" test based on extreme ranks. However, if feasible, we recommend some thousands of simulations in any case to achieve a good power and repeatability of the test. For the global "rank" envelope test, Myllymäki et al. (2017) recommended to use at least 2500 simulations for testing at the significance level alpha = 0.05 for single function tests, experimented with summary functions for point processes.

```

residual

Residual form of the functions

### **Description**

Subtract the theoretical function  $S_H_0$  or the mean of the functions in the curve set. If the curve\_set object contains already residuals  $T_i(r)$  -  $T_0(r)$ , use\_theo ignored and the same object returned.

rimov 91

### Usage

```
residual(curve_set, use_theo = TRUE)
```

### **Arguments**

an envelope object is given, it must contain the summary functions from the simulated patterns which can be achieved by setting savefuns = TRUE when

calling the envelope function.

use\_theo Whether to use the theoretical summary function or the mean of the functions in

the curve\_set.

### **Details**

The mean of the functions in the curve\_set is the mean of all functions. If use\_theo = TRUE, but the component theo does not exist in the curve\_set, the mean of the functions is used silently.

### Value

A curve set object containing residual summary functions. theo is no longer included.

rimov Year temperature curves			
	rimov	Year temperature curves	

### **Description**

Year temperature curves

# Usage

```
data("rimov")
```

### **Format**

A curve\_set object with water temperatures in 365 days of the 36 years. The component curve\_set[['r']] is a vector of days (from 1 to 365), whereas curve\_set[['obs']] contains the water temperatures such that each column gives year temperatures in a year.

### **Details**

The water temperature data sampled at the water level of Rimov reservoir in Czech republic every day for the 36 years between 1979 and 2014.

saplings

Saplings data set

### Description

Saplings data set

### Usage

```
data("saplings")
```

### **Format**

A data. frame containing the locations (x- and y-coordinates) of 123 trees in an area of 75 m  $\times$  75 m.

#### **Details**

A pattern of small trees (height <= 15 m) originating from an uneven aged multi-species broadleaf nonmanaged forest in Kaluzhskie Zaseki, Russia.

The pattern is a sample part of data collected over 10 ha plot as a part of a research program headed by project leader Prof. O.V. Smirnova.

```

subset.curve\_set

Subsetting curve sets

### **Description**

Return subsets of curve sets which meet conditions.

### Usage

```
## S3 method for class 'curve_set'
subset(x, subset, ...)
```

subset.curve\_set 95

# **Arguments**

```
x A curve_set object.subset A logical expression indicating curves to keep.... Ignored.
```
