mlr3hyperband-package mlr3hyperband: Hyperband for 'mlr3'

Description

Index

Implements hyperband method for hyperparameter tuning. Various termination criteria can be set and combined. The class 'AutoTuner' provides a convenient way to perform nested resampling in combination with 'mlr3'. The hyperband algorithm was proposed by Lisha Li, Kevin Jamieson, Giulia DeSalvo, Afshin Rostamizadeh and Ameet Talwalkar (2018) arXiv:1603.06560.

hyperband_budget 3

hyperband_bu	ıdget
--------------	-------

Hyperband Budget

Description

Calculates the total budget used by hyperband.

Usage

```
hyperband_budget(r_min, r_max, eta, integer_budget = FALSE)
```

Arguments

r_min (numeric(1))

Lower bound of budget parameter.

 r_{max} (numeric(1))

Upper bound of budget parameter.

eta (numeric(1))

Fraction parameter of the successive halving algorithm: With every stage the configuration budget is increased by a factor of eta and only the best 1/eta points are used for the next stage. Non-integer values are supported, but eta is

not allowed to be less or equal 1.

integer_budget (logical(1))

Determines if budget is an integer.

Value

```
integer(1)
```

hyperband_n_configs

Hyperband Configs

Description

Calculates how many different configurations are sampled.

Usage

```
hyperband_n_configs(r_min, r_max, eta)
```

4 hyperband_schedule

Arguments

r_min (numeric(1))

Lower bound of budget parameter.

r_max (numeric(1))

Upper bound of budget parameter.

eta (numeric(1))

Fraction parameter of the successive halving algorithm: With every stage the configuration budget is increased by a factor of eta and only the best 1/eta points are used for the next stage. Non-integer values are supported, but eta is

not allowed to be less or equal 1.

Value

integer(1)

hyperband_schedule

Hyperband Schedule

Description

Returns hyperband schedule.

Usage

```
hyperband_schedule(r_min, r_max, eta, integer_budget = FALSE)
```

Arguments

r_min (numeric(1))

Lower bound of budget parameter.

 r_{max} (numeric(1))

Upper bound of budget parameter.

eta (numeric(1))

Fraction parameter of the successive halving algorithm: With every stage the configuration budget is increased by a factor of eta and only the best 1/eta points are used for the next stage. Non-integer values are supported, but eta is

not allowed to be less or equal 1.

integer_budget (logical(1))

Determines if budget is an integer.

Value

```
data.table::data.table()
```

mlr_optimizers_hyperband

Optimizer Using the Hyperband Algorithm

Description

OptimizerHyperband class that implements hyperband optimization (HB). HB repeatedly calls SHA (OptimizerSuccessiveHalving) with different numbers of starting points. A larger number of starting points corresponds to a smaller budget allocated in the base stage. Each run of SHA within HB is called a bracket. HB considers $s_max + 1$ brackets with $s_max = floor(log(r_max / r_min, eta)$. The most explorative bracket $s = s_max$ constructs $s_max + 1$ stages and allocates the minimum budget (r_min) in the base stage. The minimum budget is increased in each bracket by a factor of eta and the number of starting points is computed so that each bracket approximately spends the same budget. Use hyperband_schedule() to get a preview of the bracket layout.

s		3		2		1		0
i	n_i	r_i	n_i	r_i	n_i	r_i	n_i	r_i
0	8	1	6	2	4	4	8	4
1	4	2	3	4	2	8		
2	2	4	1	8				
3	1	8						

s is the bracket number, i is stage number, n_i is the number of configurations and r_i is the budget allocated to a single configuration.

The budget hyperparameter must be tagged with "budget" in the search space. The minimum budget (r_min) which is allocated in the base stage of the most explorative bracket, is set by the lower bound of the budget parameter. The upper bound defines the maximum budget (r_max) which which is allocated to the candidates in the last stages.

Dictionary

This Optimizer can be instantiated via the dictionary mlr_optimizers or with the associated sugar function opt():

```
mlr_optimizers$get("hyperband")
opt("hyperband")
```

Parameters

```
eta numeric(1)
```

With every stage, the budget is increased by a factor of eta and only the best 1 / eta points are promoted to the next stage. Non-integer values are supported, but eta is not allowed to be less or equal 1.

```
sampler paradox::Sampler
```

Object defining how the samples of the parameter space should be drawn in the base stage of each bracket. The default is uniform sampling.

```
repetitions integer(1)
```

If 1 (default), optimization is stopped once all brackets are evaluated. Otherwise, optimization is stopped after repetitions runs of hyperband. The bbotk::Terminator might stop the optimization before all repetitions are executed.

Archive

The bbotk::Archive holds the following additional columns that are specific to the hyperband algorithm:

- bracket (integer(1))
 The bracket index. Counts down to 0.
- stage (integer(1))
 The stages of each bracket. Starts counting at 0.
- repetition (integer(1))
 Repetition index. Start counting at 1.

Custom Sampler

Hyperband supports custom paradox::Sampler object for initial configurations in each bracket. A custom sampler may look like this (the full example is given in the *examples* section):

```
# - beta distribution with alpha = 2 and beta = 5
# - categorical distribution with custom probabilities
sampler = SamplerJointIndep$new(list(
    Sampler1DRfun$new(params[[2]], function(n) rbeta(n, 2, 5)),
    Sampler1DCateg$new(params[[3]], prob = c(0.2, 0.3, 0.5))
))
```

Progress Bars

<code>\$optimize()</code> supports progress bars via the package **progressr** combined with a Terminator. Simply wrap the function in progressr::with_progress() to enable them. We recommend to use package **progress** as backend; enable with progressr::handlers("progress").

Logging

Hyperband uses a logger (as implemented in **lgr**) from package **bbotk**. Use lgr::get_logger("bbotk") to access and control the logger.

Super class

```

Hyperparameter Optimization with Successive Halving

Description

OptimizerSuccessiveHalving class that implements the successive halving algorithm (SHA). SHA randomly samples n candidate points and allocates a minimum budget (r_min) to all candidates. The candidates are raced down in stages to a single best candidate by repeatedly increasing the budget by a factor of eta and promoting only the best 1 / eta fraction to the next stage. This means promising points are allocated a higher budget overall and lower performing ones are discarded early on.

#' The budget hyperparameter must be tagged with "budget" in the search space. The minimum budget (r_min) which is allocated in the base stage, is set by the lower bound of the budget parameter. The upper bound defines the maximum budget (r_max) which is allocated to the candidates in the last stage. The number of stages is computed so that each candidate in base stage is allocated the minimum budget and the candidates in the last stage are not evaluated on more than the maximum budget. The following table is the stage layout for eta = 2, $r_min = 1$ and $r_max = 8$.

i	n_i	r_i
0	8	1
1	4	2
2	2	4
3	1	8

i is stage number, n_i is the number of configurations and r_i is the budget allocated to a single configuration.

Parameters

```
n integer(1)
```

Number of points in base stage.

```
eta numeric(1)
```

With every stage, the budget is increased by a factor of eta and only the best 1 / eta points are promoted to the next stage.

```
sampler paradox::Sampler
```

Object defining how the samples of the parameter space should be drawn. The default is uniform sampling.

```
repetitions integer(1)
```

If 1 (default), optimization is stopped once all stages are evaluated. Otherwise, optimization is stopped after repetitions runs of SHA. The bbotk::Terminator might stop the optimization before all repetitions are executed.

```
adjust_minimum_budget logical(1)
```

If TRUE, minimum budget is increased so that the last stage uses the maximum budget defined in the search space.

Archive

The bbotk::Archive holds the following additional columns that are specific to the successive halving algorithm:

- stage (integer(1)) Stage index. Starts counting at 0.
- repetition (integer(1)) Repetition index. Start counting at 1.

Custom Sampler

Hyperband supports custom paradox::Sampler object for initial configurations in each bracket. A custom sampler may look like this (the full example is given in the *examples* section):

```
# - beta distribution with alpha = 2 and beta = 5
# - categorical distribution with custom probabilities
sampler = SamplerJointIndep$new(list(
    Sampler1DRfun$new(params[[2]], function(n) rbeta(n, 2, 5)),
    Sampler1DCateg$new(params[[3]], prob = c(0.2, 0.3, 0.5))
))
```

Progress Bars

Description

TunerHyperband class that implements hyperband tuning (HB). HB repeatedly calls SHA (Tuner-SuccessiveHalving) with different numbers of starting configurations. A larger number of starting configurations corresponds to a smaller budget allocated in the base stage. Each run of SHA within HB is called a bracket. HB considers s_max + 1 brackets with s_max = floor(log(r_max / r_min, eta). The most explorative bracket s = s_max constructs s_max + 1 stages and allocates the minimum budget (r_min) in the base stage. The minimum budget is increased in each bracket by a factor of eta and the number of starting configurations is computed so that each bracket approximately spends the same budget. Use hyperband_schedule() to get a preview of the bracket layout.

S		3		2		1		0
i	n_i	r_i	n_i	r_i	n_i	r_i	n_i	r_i
0	8	1	6	2	4	4	8	4
1	4	2	3	4	2	8		
2	2	4	1	8				
3	1	8						

s is the bracket number, i is stage number, n_i is the number of configurations and r_i is the budget allocated to a single configuration.

The budget hyperparameter must be tagged with "budget" in the search space. The minimum budget (r_min) which is allocated in the base stage of the most explorative bracket, is set by the lower bound of the budget parameter. The upper bound defines the maximum budget (r_max) which which is allocated to the candidates in the last stages.

Subsample Budget

If the learner lacks a natural budget parameter, mlr3pipelines::PipeOpSubsample can be applied to use the subsampling rate as budget parameter. The resulting mlr3pipelines::GraphLearner is fitted on small proportions of the mlr3::Task in the first stage, and on the complete task in last stage.

Dictionary

This Optimizer can be instantiated via the dictionary mlr_optimizers or with the associated sugar function opt():

```
mlr_optimizers$get("hyperband")
opt("hyperband")
```

Parameters

```
eta numeric(1)
```

With every stage, the budget is increased by a factor of eta and only the best 1 / eta con-

figurations are promoted to the next stage. Non-integer values are supported, but eta is not allowed to be less or equal 1.

```
sampler paradox::Sampler
```

Object defining how the samples of the parameter space should be drawn in the base stage of each bracket. The default is uniform sampling.

```
repetitions integer(1)
```

If 1 (default), optimization is stopped once all brackets are evaluated. Otherwise, optimization is stopped after repetitions runs of hyperband. The bbotk::Terminator might stop the optimization before all repetitions are executed.

Archive

The mlr3tuning::ArchiveTuning holds the following additional columns that are specific to the hyperband algorithm:

```
    bracket (integer(1))
    The bracket index. Counts down to 0.
```

- stage (integer(1))
 The stages of each bracket. Starts counting at 0.
- repetition (integer(1))
 Repetition index. Start counting at 1.

Custom Sampler

Hyperband supports custom paradox::Sampler object for initial configurations in each bracket. A custom sampler may look like this (the full example is given in the *examples* section):

```
# - beta distribution with alpha = 2 and beta = 5
# - categorical distribution with custom probabilities
sampler = SamplerJointIndep$new(list(
    Sampler1DRfun$new(params[[2]], function(n) rbeta(n, 2, 5)),
    Sampler1DCateg$new(params[[3]], prob = c(0.2, 0.3, 0.5))
))
```

Progress Bars

<code>\$optimize()</code> supports progress bars via the package **progressr** combined with a Terminator. Simply wrap the function in progressr::with_progress() to enable them. We recommend to use package **progress** as backend; enable with progressr::handlers("progress").

Parallelization

This hyperband implementation evaluates hyperparameter configurations of equal budget across brackets in one batch. For example, all configurations in stage 1 of bracket 3 and stage 0 of bracket 2 in one batch. To select a parallel backend, use future::plan().

Logging

Hyperband uses a logger (as implemented in lgr) from package bbotk. Use lgr::get_logger("bbotk") to access and control the logger.

Super classes

Hyperparameter Tuning with Successive Halving

Description

}

TunerSuccessiveHalving class that implements the successive halving algorithm (SHA). SHA randomly samples n candidate hyperparameter configurations and allocates a minimum budget (r_min) to all candidates. The candidates are raced down in stages to a single best candidate by repeatedly increasing the budget by a factor of eta and promoting only the best 1 / eta fraction to the next stage. This means promising hyperparameter configurations are allocated a higher budget overall and lower performing ones are discarded early on.

The budget hyperparameter must be tagged with "budget" in the search space. The minimum budget (r_min) which is allocated in the base stage, is set by the lower bound of the budget parameter. The upper bound defines the maximum budget (r_max) which is allocated to the candidates in the last stage. The number of stages is computed so that each candidate in base stage is allocated the minimum budget and the candidates in the last stage are not evaluated on more than the maximum budget. The following table is the stage layout for eta = 2, $r_min = 1$ and $r_max = 8$.

i	n_i	r_i
0	8	1
1	4	2
2	2	4
3	1	8

i is stage number, n_i is the number of configurations and r_i is the budget allocated to a single configuration.

Subsample Budget

If the learner lacks a natural budget parameter, mlr3pipelines::PipeOpSubsample can be applied to use the subsampling rate as budget parameter. The resulting mlr3pipelines::GraphLearner is fitted on small proportions of the mlr3::Task in the first stage, and on the complete task in last stage.

Parameters

```
n integer(1)
Number of candidates in base stage.
eta numeric(1)
```

With every stage, the budget is increased by a factor of eta and only the best 1 / eta candi-

dates are promoted to the next stage. Non-integer values are supported, but eta is not allowed to be less or equal 1.

```
sampler paradox::Sampler
```

Object defining how the samples of the parameter space should be drawn. The default is uniform sampling.

```
repeats logical(1)
```

If FALSE (default), SHA terminates once all stages are evaluated. Otherwise, SHA starts over again once the last stage is evaluated.

```
adjust_minimum_budget logical(1)
```

If TRUE, minimum budget is increased so that the last stage uses the maximum budget defined in the search space.

Archive

The mlr3tuning::ArchiveTuning holds the following additional columns that are specific to the successive halving algorithm:

```
• stage (integer(1))
Stage index. Starts counting at 0.
```

repetition (integer(1))
 Repetition index. Start counting at 1.

Custom Sampler

Hyperband supports custom paradox::Sampler object for initial configurations in each bracket. A custom sampler may look like this (the full example is given in the *examples* section):

```
# - beta distribution with alpha = 2 and beta = 5
# - categorical distribution with custom probabilities
sampler = SamplerJointIndep$new(list(
    Sampler1DRfun$new(params[[2]], function(n) rbeta(n, 2, 5)),
    Sampler1DCateg$new(params[[3]], prob = c(0.2, 0.3, 0.5))
))
```

Progress Bars

<code>\$optimize()</code> supports progress bars via the package **progressr** combined with a Terminator. Simply wrap the function in progressr::with_progress() to enable them. We recommend to use package **progress** as backend; enable with progressr::handlers("progress").

Parallelization

The hyperparameter configurations of one stage are evaluated in parallel with the **future** package. To select a parallel backend, use future::plan().

Logging

Hyperband uses a logger (as implemented in **lgr**) from package **bbotk**. Use lgr::get_logger("bbotk") to access and control the logger.
